THE LANCET

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology, Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY

VOL. CCXII.

VOL. I. FOR 1927

228

ONE HUNDRED AND FIFTH YEAR

EDITED BY

SIR SQUIRE SPRIGGE, M.A., M.D. CANTAB., F.R.C.S. ENG.,

AND

EGBERT MORLAND, B.Sc., M.B. LOND., M.D. BERNE

LONDON
PUBLISHED BY THE PROPRIETORS THE LANCET LIMITED No. 423, STRAND, AND No. 1, BEDFORD STREET STRAND, IN THE COUNTY OF LONDON, AND PRINTED BY HAZELL WATSON & VINEY, LD., 52, LONG ACRE W.C. 2.

MCMXXVII.

REFERENCES AND ABBREVIATIONS

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such for instance as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes Glycosuria and Sugar, Eye, Ophthalmic, and Vision Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c , &c , and that regional headings are more frequently used than pathological Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading, and Medical Societies, which are separately indexed under Societies All Universities are indexed under the word University (A) = Annotation, (C) = Correspondence (N I) = New Inventions, (L A) = Leading Article, (M L) = Medico-legal, (M T T) = Modern Technique in Treatment, (O) = Obituary (P I) = Parliamentary Intelligence, (R) = Review, (R and A R) = Reports and Analytical Records, and (C M P) = Conduct of Medical Practice

CONCORDANCE

Purvis Oration

ON

PROGNOSIS.

Delivered on Dec 10th before the West Kent Medico-Chirurgical Society

By ROBERT HUTCHISON, M D Edin, F R C P Lond,

PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

OF the three great divisions of practical medicine—diagnosis, prognosis, and treatment—prognosis is certainly the most difficult It demands as much knowledge and power of observation as diagnosis, and even more experience and judgment Experience, indeed, is, perhaps, what the prognostician requires most of all "When old experience doth attain to something like prophetic strain," for the ability accurately to foretell the course of a disease can only be acquired by watching a large number of cases throughout their whole course In this respect the family practitioner is much more fortunately placed than the consultant, for, as Sir Andrew Clark remarked, "if a consultant cures a patient the latter rarely returns to him; if he fails to cure, the patient never does" Even the hospital physician finds it very difficult to watch his cases to the end. As a rule he sees only one segment of the orbit of the disease, and that is all; of what went before and what followed after he knows nothing. The more general introduction of follow-up departments, such as some of the surgeons have started, would do much to remedy this defect. but even a large experience in prognosis may be rendered useless by changes in the type of disease or by the introduction of new methods of treatment Scarlatina, for example, is a much milder disease than it was a generation or two ago, and its prognosis proportionately better, whereas in the case of measles the exact opposite is true, whilst the discovery of insulin has entirely altered the prognosis in diabetes

Perhaps because of the inherent difficulties of the subject, prognosis has been less carefully studied than either diagnosis or treatment, and I know of no really good book upon it in the English language; indeed, until comparatively recently there was no book of any kind devoted entirely to prognosis since the Hippocratic writings, and by prognosis Hippocrates meant, of course, something wider than we mean by it now. There is, it is true, a great deal of material, statistical and other, bearing upon the prognosis of particular diseases scattered through current medical literature, but very little of it has found its way into the text-books, and any young physician who was prepared to devote a lifetime to the collection of his facts and observations might in his later years produce a really good treatise on prognosis which would make the whole profession his debtor.

In spite, however, of the difficulties of the subject, it is certainly a good mental training to try to form as accurate a forecast as one can of the course of every case of serious disease which one has to deal with, even although the event will inevitably falsify one's anticipations with disappointing frequency.

Prognosis, rightly understood, is not merely a question of telling whether a patient will survive or not—"immediate" prognosis, as it is called. It is much wider than that It should include the consideration of how long life is likely to be prolonged, and, in the event of a fatal issue, the mode of death, or, if recovery is anticipated, when it will take place, whether it will be complete, at what period the patient will be fit for work, and so forth, all of which considerations may be grouped under the term "remote" prognosis It includes, in short, a complete foreknowledge of the whole course of events

In practice one has to form a prognosis in three sets of circumstances, each governed by different conditions. (1) Where the question of the expectation of life or health arises in persons presumably healthy; (2) in acute self-limited disease, (3) in chronic disease, whether curable or inevitably progressive We may consider the prognostic indications in each of these circumstances separately

PROGNOSIS IN THE HEALTHY

Prognosis in the presumably healthy is the essential business of the examiner for life assurance, and its object is to forecast as accurately as possible how long the individual is likely to live One cannot, of course, allow for all "the changes and chances of this mortal life," but some considerations are of special importance First of these, naturally, is the subject's present age and also, seeing that longevity is largely a matter of heredity, the age at death of his immediate relatives Nothing, in fact, contributes so much to length of days as a wise choice of ancestors Much importance, too, will be attached to occupation and habits On the other hand, questions of build and physique are probably of much less moment than is usually supposed. Pale, weedy subjects often potter on to a green old age, improving in health as they go, whilst the florid and muscular succumb in middle life to acute disease or a cerebral hæmorrhage Thin people are better lives than fat, for the more rotund the figure the more rapidly does one roll down the hill of life The state of the chief organs will rightly demand attention, especially the condition of the heart and arteries, the height of the blood pressure, the presence or absence of emphysema, and the efficiency of the kidneys Functional dyspepsia, however, is no bar to long life, indeed, rather the reverse. On one very important matter bearing upon life expectation it is, unfortunately, difficult to form an opinion unless one happens to be the patient's family doctor—I mean the capacity of "resistance" to acute infections. The general appearance of the subject is no guide here: Healthy-seeming, robust individuals, indeed, often offer much less "resistance" than those of a more fragile type, except, perhaps, to infection by tuberculosis Putting aside this difficulty, it is only by the careful consideration of such points as I have indicated that one is able to form a reasonably accurate estimate of what, barring accidents, is the individual's chance of surviving to the natural term of human life. If, however, he is found not to be really healthy, but to present signs of incipient or old-standing disease in any of the important organs the prognosis must be arrived at on the same considerations as in a case of chronic disease About this I shall have something to say immediately

PROGNOSIS IN ACUTE DISEASE

Prognosis in acute self-limited disease—not of a necessarily fatal sort—resolves itself into the question, Can the patient be kept alive until the malady has run its course? In arriving at a judgment upon this question the patient's age is, again, of first importance, for in acute disease, of which pneumonia may be taken as a typical example, age has more to do with the chance of recovery than anything else To quote Sir Andrew Clark once more, "No healthy person below the age of 40 ought ever to die of acute disease," and although, like most medical aphorisms, this has to be taken with a grain of salt, it does embody the fundamental truth that youth is the patient's chief ally. In this connexion I once investigated the mortality of pneumonia at the London Hospital over a period of ten years, the statistics covering some hundreds of cases, and found that the death-rate increased by about 10 per cent for every decade of advance in age of the patient Compared with age no other factor in the case seemed much to affect the outlook. One must take into account, of course, the patient's physiological age as well as his age by the calendar, and it is assumed that up to the time of the illness he has been in good health Acute disease supervening upon some chronic disorder is always more dangerous On the other hand, the patient's "physique" is no more a guide to his chances of overcoming an acute infection than it is to his prospects of longevity in health The condition of the chief organs is of the first significance, those which most demand attention being the heart, kidneys, and lungs, in that order of importance Much depends upon the heart, for, in acute disease, a patient "lives as long as his left ventricle" Unfortunately, we have no means of directly estimating the staying power of the heart, some such means is a great desideratum in all prognosis Some clinical indications are of help, however Thus a steadily increasing rate of the pulse with a tendency for it to become irregular when the patient turns over in bed is a disquieting sign, and so is the disappearance of the first sound at the apex A wide departure from the normal pulse-respiration ratio in either direction should always cause anxiety. A low blood pressure is unfavourable, and in such a disease as pneumonia there is no better guide to prognosis than the relation between the systolic pressure and the pulse rate So long as the pressure (in millimetres) is higher than the pulse-rate per minute, things are going well, if the ratio is reversed then the outlook is bad Such a sign of general circulatory failure as coldness of the extremities is always a very grave portent

Some general indications may also aid one Thus a moist skin and a moist tongue are of better omen than dryness of these organs, and constipation is better than diarrhœa Ability to take food is always favourable, and the physicians of former days attached great importance to it Heberden considered loss of appetite "the despair of Nature, yielding up her power to the force of the disease," On the other hand, the temperature is of much less prognostic value than a patient's friends usually suppose, and all that one can say of it is that the gravity of a high temperature is least in a child and greatest in old age The degree to which a patient is maintaining or losing strength may be judged to some extent from his position in bed A persistent dorsal decubitus, and, still more, a tendency to slip down in the bed, are bad signs, whilst an ability to lie on the side is favourable The grip of the hand is a useful gauge of strength, and so is the timbre of the voice I was once told by a clergyman of large experience in visiting the sick that he could tell at once by the degree of resonance in a patient's voice whether he was better or worse. A consideration of all these factors taken in conjunction with what is known as to the statistical rate of recovery in the particular disease will usually enable one to form a fairly trustworthy estimate of the patient's chances[1] What is most likely to falsify one's hopes is the supervention of sudden heart failure, but this is unforeseeable

PROGNOSIS IN CHRONIC DISEASE

In forming a prognosis in chronic cases the first consideration is whether the malady is of its very nature a mortal one or whether it is susceptible of cure, or at least of arrest In cases of the former category, of which lymphadenoma may be taken as an example, the average duration of the disease as shown by statistics will enable one to form at least a rough estimate of the period to which the patient's life is likely to be prolonged, but his general condition must also be taken into consideration In wasting disorders, for instance, a well-nourished patient is likely to last longer than one who is already emaciated Much, also, will depend upon the patient's "resistance" and upon the degree of "virulence" of the disease in his particular case, and these important factors can often only be appreciated by watching the progress of events for a period

In chronic diseases which are capable of arrest, or even cure, such as pulmonary tuberculosis and diabetes, the resistance of the patient and the type of the disease play such a preponderating part that it is never wise to make a forecast until the patient has been under observation for some time, and it is in such cases that hasty prognosis is most to be deprecated Apart from this the same general considerations must guide one, as in cases of chronic incurable disease, whilst much importance must also be attached to the presence or absence of "complications" In no class of case, also, have the patient's habits and surroundings a greater influence on the march of events

CAUSES OF ERROR

We may now consider briefly the chief causes of error in prognosis Easily first amongst these is wrong *diagnosis* I remember a good many years ago seeing in consultation a lady who had been suffering for some months from symptoms of dyspepsia and had lately taken to vomiting all food On examination of the abdomen I felt a large, hard and irregular lump in the epigastrium I concluded that the patient was suffering from cancer of the stomach, and told her husband that she could not recover A few days later, however, an enema removed a big scybalous mass from the bowel, the tumour disappeared, and with it all the patient's symptoms! My prognosis here was wrong because my diagnosis was wrong, and so it must ever be, for accurate prognosis depends first and foremost upon exact diagnosis, and it will be found, I think, that much uncertainty as to prognosis in practice is really due to the fact that the doctor is not quite sure what he is dealing with

Another source of error is the attaching of too much importance to physical signs and too little to the patient's general condition This usually leads one to make too gloomy a forecast In the same way what has been called the "post-mortem type of mind" in a doctor tends to make him take too serious a view of disease He has a very clear vision of the structural changes in the patient's organs, but is apt to forget how long a hopelessly damaged machine is able to go on running

A common mistake, which can hardly be avoided altogether, is failure to allow for possible complications—for the supervention of embolism or pulmonary œdema or a sudden hæmorrhage, and so forth Such events are so unpredictable that it is always justifiable—and wise—to hedge by saying "the outlook is good—*provided no complication arises*" Our inability to estimate the reserve power of the heart which has been already deplored, is another and fertile source of falsification of the best-laid prognoses In the present state of our knowledge this source of error is, apparently, unavoidable

Lastly, it must be frankly recognised that a wrong prognosis is often the result of a failure or refusal to face the facts Some doctors, out of kindness of heart or from a fatuous sort of optimism or inability to admit that they are beaten, keep on promising recovery when a cooler judgment would recognise that the game was up This is an error, albeit an excusable one, for it is only by an entirely judicial weighing of the evidence, without bias one way or the other, that accuracy in prognosis is to be reached It is bad to "give up" a patient too soon, but, from the point of view of prognosis, it is almost as bad to place too much faith in the popular adage, "While there is life there is hope"

Apropos of this aspect of our subject, it might be supposed that a doctor's own temperament would influence his prognosis, that the optimist would tend to take a hopeful view, and the pessimist a gloomy one I doubt, however, whether this is so At any rate, so far as I have been able to observe, a man may be a pessimist in his general outlook on life and yet be as hopeful in his attitude to disease as anyone else Young men, indeed, who ought to be optimists, are generally more gloomy prognosticians than the old, for, like the post mortem-minded doctors spoken of above, they have not learnt by experience how well a patient can get on even although his organs are seriously impaired I have an impression, too, that women tend to be less inclined to the rosy view than men—but this may be the result of natural timidity or over-conscientiousness Anyhow, one should always try (in the words of *Punch*) to be neither a "pooh-pooher" nor a "wind-upper"

---

[1] It need hardly be said that a knowledge of the statistical rate of recovery is of only limited value in *individual* prognosis If, for example, a patient is told that the mortality rate of his disease is 30 per cent he naturally wants to know whether *he* is likely to be one of the unfortunate 30 It does, however give a rough indication of the odds against which he has to fight

What the Patient Should be Told

Having formed a prognosis the question arises, Should one communicate it to the patient, or, in other words, "Should the doctor tell?" Now the first thing to be remarked on this question is that a patient is often curiously incurious as to the outcome of his disease—he is much more likely to be interested in its cause or its treatment Whether this may be for the reason that he is afraid to ask I do not know, but the fact remains, and it is more likely to be the relatives who will inquire as to his chances One must be on the watch, however, as Dr H W Gardner has said, against unconscious telling "Beware," as he puts it, "the unguarded word, the unguarded hesitation, or even the unconscious sigh," any of which may "give the show away" As to conscious and deliberate telling, it need hardly be said that if the prognosis is favourable the question does not arise, for nothing but good can then come from declaring one's opinion, although it is always prudent, as I have pointed out before, to qualify it by the rider "provided there are no complications," and to remember the wise saying that in matters of prognosis a doctor should never say "always" or "never" An unfavourable verdict, however, is a totally different matter, and opinions differ as to what course one should take about it Dr Samuel Johnson had no doubt on the point "I deny," he said, in his downright way, "the lawfulness of telling a lie to a sick man for fear of alarming him You have no business with consequences you are to tell the truth Besides, you are not sure what effect your telling him that he is in danger may have It may bring his distemper to a crisis, and that may cure him" With all respect to the great moralist, however, the matter is not quite so simple as that The doctor *has* a responsibility for the consequences of what he says to a patient, and so far from a gloomy prognosis "bringing his distemper to a crisis," it is much more likely both to depress the patient's power of opposing the disease, and so, perhaps, turn the scale against him, and to discourage those in attendance with the knowledge that they are fighting a losing battle We must never forget that, as Coleridge said, "he is the best physician who is the best inspirer of hope", or that, in Biblical language, "We are saved through Hope" On the other hand, it may be desirable that the patient should know that he is in danger He might wish, for instance, to make a disposition of his worldly goods, to send for someone whom he loves, or even, in the old phrase, "to make his peace with God" In these circumstances the practice with most doctors, and it is probably on the whole the best, is to take some discreet relative into confidence and to leave it to him or her to tell the patient if it is thought wise

On the other hand, if the patient insists on knowing the truth, the whole truth, and nothing but the truth about his condition, one is bound to tell him, for, as someone has said, "*one must not lie to a dying man*", but it is our bounden duty in such circumstances to try "to speak the truth with kindness" I have been surprised, as a rule, to find how well the sentence is taken Patients are not such cowards as their friends are apt to imagine, and the verdict is often received almost with a measure of relief, for the patient has probably long suspected the true state of affairs, and the doctor's confirmation of his suspicions puts a final end to all tormenting uncertainty It need hardly be said, however, that one should not communicate a fatal prognosis even to the friends, and still less to the patient himself, unless one is sure "beyond a peradventure," and it may be advisable in many cases where one is pressed for an opinion, to leave a loophole both to serve for one's own escape if need be and to admit a ray of hope to the bedside meantime For it must never be forgotten that a bad prognosis which proves mistaken is less likely to be forgiven—and rightly so—than a good prognosis which is falsified by the event Further, one should never aim at an impossible degree of accuracy It may be justifiable to foretell a fatal issue, but one is rarely justified in saying exactly when it will take place The guess is almost certain to be wrong, and the miscalculation is sure to be cast up against one afterwards As an experienced practitioner once said "If your forecast is correct you get no credit for it, and if it is wrong you are thought to be a damned fool" For the same reason it is never wise to try to express the prognosis mathematically and to say that the chances of recovery are 1 in 20, or 1 in 100, and so on, even though the friends sometimes ask one to do this To speak thus may give an impression of accurate knowledge, but the impression is really false, for there are too many uncertain factors in the calculation The method may sometimes be of use in expressing an otherwise healthy person's chance of surviving a particular operation, the mortality of which has been established on a wide statistical basis, but in ordinary medical prognosis it should be avoided

Finally, there can be no doubt that to "drop a brick" (as medical students say) in prognosis does more harm to a doctor's reputation than an error in diagnosis This, of course, is quite unjust, for a wrong diagnosis may cost a patient his life, which can hardly be said of a prognosis however false It must be remembered, however, that the patient and his friends have often only a vague idea of what the diagnosis really is, and it is easy to cover one's tracks when making it, whereas everyone knows whether the patient has survived or not It is wise, therefore, not to prophesy unnecessarily, but at the same time to remember that on the whole a good prognosis pays best both for the patient and for the doctor, and so if one *must* prophesy to try, if at all possible, to prophesy smooth things

(*From the Wards and the Department of Biochemistry, Middlesex Hospital*)

It has become a commonplace of medical teaching that nephritis usually manifests itself in one of two forms (1) the type characterised by œdema, and (2) the type associated with high blood pressure and other cardiovascular phenomena, nitrogen retention in the blood, and uræmic symptoms These two clinical types are the néphrite hydropigène and the néphrite azotémique of French observers It is likewise a commonplace that, whereas pure examples of one or other of these types are frequently seen, it occasionally happens that one form may merge into the other, or that at least some degree of one type may become grafted upon a case exhibiting chiefly the other group of symptoms

The distinction between the two types of disorder can be set out as follows —

I	II
Œdema	No œdema except from cardiac failure
Normal blood pressure	Raised blood pressure
No cardiac hypertrophy	Cardiac hypertrophy
Oliguria	Polyuria or suppression of urine
Marked albuminuria	Slight albuminuria
Normal excretion of urea	Urea excreted in low concentration
High specific gravity urine	Low specific gravity urine
No nitrogen retention.	Nitrogen retention
No signs or symptoms of uræmia	Uræmia common

overcoming an acute infection than it is to his prospects of longevity in health The condition of the chief organs is of the first significance, those which most demand attention being the heart, kidneys, and lungs, in that order of importance Much depends upon the heart, for, in acute disease, a patient "lives as long as his left ventricle" Unfortunately, we have no means of directly estimating the staying power of the heart; some such means is a great desideratum in all prognosis Some clinical indications are of help, however. Thus a steadily increasing rate of the pulse with a tendency for it to become irregular when the patient turns over in bed is a disquieting sign, and so is the disappearance of the first sound at the apex. A wide departure from the normal pulse-respiration ratio in either direction should always cause anxiety. A low blood pressure is unfavourable, and in such a disease as pneumonia there is no better guide to prognosis than the relation between the systolic pressure and the pulse rate So long as the pressure (in millimetres) is higher than the pulse-rate per minute, things are going well; if the ratio is reversed then the outlook is bad Such a sign of general circulatory failure as coldness of the extremities is always a very grave portent

Some general indications may also aid one Thus a moist skin and a moist tongue are of better omen than dryness of these organs, and constipation is better than diarrhœa Ability to take food is always favourable, and the physicians of former days attached great importance to it Heberden considered loss of appetite "the despair of Nature, yielding up her power to the force of the disease," On the other hand, the temperature is of much less prognostic value than a patient's friends usually suppose, and all that one can say of it is that the gravity of a high temperature is least in a child and greatest in old age The degree to which a patient is maintaining or losing strength may be judged to some extent from his position in bed A persistent dorsal decubitus, and, still more, a tendency to slip down in the bed, are bad signs, whilst an ability to lie on the side is favourable The grip of the hand is a useful gauge of strength, and so is the timbre of the voice I was once told by a clergyman of large experience in visiting the sick that he could tell at once by the degree of resonance in a patient's voice whether he was better or worse. A consideration of all these factors taken in conjunction with what is known as to the statistical rate of recovery in the particular disease will usually enable one to form a fairly trustworthy estimate of the patient's chances[1] What is most likely to falsify one's hopes is the supervention of sudden heart failure, but this is unforeseeable

PROGNOSIS IN CHRONIC DISEASE

In forming a prognosis in chronic cases the first consideration is whether the malady is of its very nature a mortal one or whether it is susceptible of cure, or at least of arrest In cases of the former category, of which lymphadenoma may be taken as an example, the average duration of the disease as shown by statistics will enable one to form at least a rough estimate of the period to which the patient's life is likely to be prolonged, but his general condition must also be taken into consideration In wasting disorders, for instance, a well-nourished patient is likely to last longer than one who is already emaciated Much, also, will depend upon the patient's "resistance" and upon the degree of "virulence" of the disease in his particular case, and these important factors can often only be appreciated by watching the progress of events for a period

In chronic diseases which are capable of arrest, or even cure, such as pulmonary tuberculosis and diabetes, the resistance of the patient and the type of the disease play such a preponderating part that it is never wise to make a forecast until the patient has been under observation for some time, and it is in such cases that hasty prognosis is most to be deprecated Apart from this the same general considerations must guide one, as in cases of chronic incurable disease, whilst much importance must also be attached to the presence or absence of "complications" In no class of case, also, have the patient's habits and surroundings a greater influence on the march of events

CAUSES OF ERROR.

We may now consider briefly the chief causes of error in prognosis Easily first amongst these is wrong *diagnosis*. I remember a good many years ago seeing in consultation a lady who had been suffering for some months from symptoms of dyspepsia and had lately taken to vomiting all food On examination of the abdomen I felt a large, hard and irregular lump in the epigastrium I concluded that the patient was suffering from cancer of the stomach, and told her husband that she could not recover A few days later, however, an enema removed a big scybalous mass from the bowel, the tumour disappeared, and with it all the patient's symptoms! My prognosis here was wrong because my diagnosis was wrong, and so it must ever be, for accurate prognosis depends first and foremost upon exact diagnosis, and it will be found, I think, that much uncertainty as to prognosis in practice is really due to the fact that the doctor is not quite sure what he is dealing with

Another source of error is the attaching of too much importance to physical signs and too little to the patient's general condition This usually leads one to make too gloomy a forecast In the same way what has been called the "*post-mortem* type of mind" in a doctor tends to make him take too serious a view of disease He has a very clear vision of the structural changes in the patient's organs, but is apt to forget how long a hopelessly damaged machine is able to go on running

A common mistake, which can hardly be avoided altogether, is failure to allow for possible complications—for the supervention of embolism or pulmonary œdema or a sudden hæmorrhage, and so forth Such events are so unpredictable that it is always justifiable—and wise—to hedge by saying "the outlook is good—*provided no complication arises*" Our inability to estimate the reserve power of the heart which has been already deplored, is another and fertile source of falsification of the best-laid prognoses In the present state of our knowledge this source of error is, apparently, unavoidable

Lastly, it must be frankly recognised that a wrong prognosis is often the result of a failure or refusal to face the facts Some doctors, out of kindness of heart or from a fatuous sort of optimism or inability to admit that they are beaten, keep on promising recovery when a cooler judgment would recognise that the game was up This is an error, albeit an excusable one, for it is only by an entirely judicial weighing of the evidence, without bias one way or the other, that accuracy in prognosis is to be reached It is bad to "give up" a patient too soon, but, from the point of view of prognosis, it is almost as bad to place too much faith in the popular adage, "While there is life there is hope"

Apropos of this aspect of our subject, it might be supposed that a doctor's own temperament would influence his prognosis, that the optimist would tend to take a hopeful view, and the pessimist a gloomy one I doubt, however, whether this is so At any rate, so far as I have been able to observe, a man may be a pessimist in his general outlook on life and yet be as hopeful in his attitude to disease as anyone else Young men, indeed, who ought to be optimists, are generally more gloomy prognosticians than the old, for, like the post mortem-minded doctors spoken of above, they have not learnt by experience how well a patient can get on even although his organs are seriously impaired. I have an impression, too, that women tend to be less inclined to the rosy view than men—but this may be the result of natural timidity or over-conscientiousness Anyhow, one should always try (in the words of *Punch*) to be neither a " pooh-poober " nor a " wind-upper "

---

[1] It need hardly be said that a knowledge of the statistical rate of recovery is of only limited value in *individual* prognosis If, for example, a patient is told that the *mortality* rate of his disease is 30 per cent he naturally wants to know whether *he* is likely to be one of the unfortunate 30 It does, however give a rough indication of the *odds against* which he has to fight

What the Patient Should be Told

Having formed a prognosis the question arises, *Should one communicate it to the patient, or, in other* words " Should the doctor tell ? " Now the first thing to be remarked on this question is that a patient is often curiously incurious as to the outcome of his disease—he is much more *likely* to be interested in its cause or its treatment Whether this may be for the reason that he is afraid to ask I do not know, but the fact remains and it is more likely to be the relatives who will inquire as to his chances One must be on the watch, however, as Dr H W Gardner has said, against unconscious telling " Beware " as he puts it, " the unguarded word, the unguarded hesitation, or even the unconscious sigh," any of which may " give the show away " As to conscious and deliberate telling, it need hardly be said that if the prognosis is favourable the question does not arise for nothing but good can then come from declaring one's opinion although it is always prudent, as I have pointed out before, to qualify it by the rider " provided there are no complications," and to remember the wise saying that in matters of prognosis a doctor should never say " always " or " never " An unfavourable verdict, however, is a totally different matter, and opinions differ as to what course one should take about it Dr Samuel Johnson had no doubt on the point " I deny " he said, in his down right way, " the lawfulness of telling a lie to a sick man for fear of alarming him. You have no business with consequences you are to tell the truth. Besides, you are not sure what effect your telling him that he is in danger may have It may bring his distemper to a crisis, and that may cure him ' With all respect to the great moralist however, the matter is not quite so simple as that. The doctor *has* a responsibility for the consequences of what he says to a patient, and so far from a gloomy prognosis " bringing his distemper to a crisis," it is much more likely both to depress the patient's power of opposing the disease, and so perhaps, turn the scale against him, and to discourage those in attendance with the knowledge that they are fighting a losing battle. We must never forget that as Coleridge said, " he is the best physician who is the best inspirer of hope " ; or that, in Biblical language, " We are saved through Hope." On the other hand, it may be desirable that the patient should know that he is in danger He might wish, for instance, to make a disposition of his worldly goods, to send for someone whom he loves, or even, in the old phrase, " to make his peace with God " In these circumstances the practice with most doctors, and it is probably on the whole the best is to take some discreet relative into confidence and to leave it to him or her to tell the patient if it is thought wise

On the other hand, if the patient insists on knowing the truth, the whole truth, and nothing but the truth about his condition, one is bound to tell him, for, as someone has said, " one must not lie to a dying man " , but it is our bounden duty in such circumstances to try " to speak the truth with kindness " I have been surprised, as a rule, to find how well the sentence is taken Patients are not such cowards as their friends are apt to imagine, and the verdict is often received almost with a measure of relief, for the patient has probably long suspected the true state of affairs, and the doctor's confirmation of his suspicions puts a final end to all tormenting uncertainty. It need hardly be said, however, that one should not communicate a fatal prognosis even to the friends, and still less to the patient himself, unless one is sure " beyond a peradventure," and it may be advisable in many cases where one is pressed for an opinion, to leave a loophole both to serve for one's own escape if need be and to admit a ray of hope to the bedside meantime. For it must never be forgotten that a bad prognosis which proves mistaken is less likely to be forgiven—and rightly so—than a good prognosis which is falsified by the event Further, one should never aim at an impossible degree of accuracy. It may be justifiable to foretell a fatal issue but one is rarely justified in saying exactly when it will take place The guess is almost certain to be wrong, and the miscalculation is sure to be cast up against one afterwards As an *experienced practitioner once said* " *If your forecast* is correct you get no credit for it, and if it is wrong you are *thought to be a damned fool* " For the same reason it is never wise to try to express the prognosis *mathematically and to say that the* chances of recovery are 1 in 20, or 1 in 100, and so on, even though the *friends* sometimes *ask* one to do this To speak thus may give an impression of accurate knowledge, but the impression is really false, for there are too many uncertain factors in the calculation The method may sometimes be of use in expressing an otherwise healthy person's chance of surviving a particular operation the mortality of which has been established on a wide statistical basis, but in ordinary medical prognosis it should be avoided

Finally, there can be no doubt that to " drop a brick " (as medical students say) in prognosis does more harm to a doctor's reputation than an error in diagnosis This, of course, is quite unjust, for a wrong diagnosis may cost a patient his life, which can hardly be said of a prognosis however false It must be remembered, however, that the patient and his friends have often only a vague idea of what the diagnosis really is, and it is easy to cover one's tracks when making it, whereas everyone knows whether the patient has survived or not It is wise, therefore, not to prophesy unnecessarily but at the same time to remember that on the whole a good prognosis pays best both for the patient and for the doctor, and so if one *must* prophesy to try, if at all possible, to prophesy smooth things

PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF LONDON AND MIDDLESEX HOSPITAL.

(*From the Wards and the Department of Biochemistry, Middlesex Hospital*)

It has become a commonplace of medical teaching that nephritis usually manifests itself in one of two forms (1) the type characterised by œdema, and (2) the type associated with high blood pressure and other cardiovascular phenomena nitrogen retention in the blood, and uræmic symptoms These two clinical types are the néphrite hydropigène and the néphrite azotémique of French observers It is likewise a commonplace that, whereas *pure examples* of one or other of these types are frequently seen, it occasionally happens that one form may merge into the other, or that at least some degree of one type may become grafted upon a case exhibiting chiefly the other group of symptoms

The distinction between the two types of disorder can be set out as follows —

I.	II.
Œdema.	No œdema except from cardiac failure
Normal blood pressure	Raised blood pressure
No cardiac hypertrophy.	Cardiac hypertrophy.
Oliguria.	Polyuria or suppression of urine
Marked albuminuria.	Slight albuminuria
Normal excretion of urea	Urea excreted in low concentration.
High specific gravity urine	Low specific gravity urine
No nitrogen retention.	Nitrogen retention
No signs or symptoms of uræmia	Uræmia common

Whilst many of the clinical features of these two syndromes have been recognised since the days of Bright, the interrelation of the two has been the subject of such confusion, and the relation of each to the macroscopic appearances of the kidneys seen at autopsy has often been so contradictory that nephritis has remained a subject of the utmost complexity to all students of medicine, whether qualified or unqualified

If the clinical and laboratory features of the dropsical type of renal disorder are examined, it is apparent that the evidences of defective kidney function are not considerable There is albuminuria, often of massive proportions, which seems inexplicable on any ground save that of damage to the kidneys, there is marked œdema, but this is a symptom which cannot readily be produced experimentally by any action on the kidneys; and beyond these symptoms we have a series of findings almost entirely negative, which points to the renal function being generally efficient rather than deranged.

The Conception of Nephrosis

In recent years the term nephrosis has occurred with increasing frequency in medical literature It appears to have been originally suggested by F Muller[1] to emphasise those types of renal disease in which purely degenerative rather than "inflammatory" lesions are conspicuous, the term nephritis being reserved for the latter. German writers have gradually accepted this conception as one of primary pathological importance, and the work of Volhard and Fahr[2] and of Munk[3] has done much to establish the term and harmonise it with certain clinical findings

It may be apposite at this point to recall the large number of examples of supposed renal disorders in which actual inflammatory reaction of the kidney tissue cannot be proved; many of the "renal" complications of pregnancy, the majority of cases of "hydropiginous" or "dropsical" nephritis in children, and probably most of these cases of "nephritis" seen during the late war fall into this group, the microscopic appearances in the kidneys being almost purely degenerative According to the conception of Munk,[4] all renal disease with œdema apart from heart failure should be classed as nephrosis, whilst cases with hæmaturia, uræmia, and cardiovascular complications constitute true nephritis When a water-logged patient gets an attack of hæmaturia, and the blood pressure rises and nitrogen retention appears, it is nephritis complicating nephrosis, when, on the other hand, a patient after a febrile hæmaturia with transient hyperpiesia passes into a condition of anasarca, that is nephrosis supervening upon nephritis It must be noted that in contrast to these views many British pathologists hold that the ætiology of all kidney disease is toxic, degeneration being always the first effect and reaction a later but not inevitable consequence, and that degeneration is itself an inflammatory phenomenon, whether followed by reaction or not

The Blood-lipoids in Renal Disorders

In 1911 Chauffard, Laroche[5] and Grigaut[6] observed that in nephritic œdema there was frequently excess of cholesterol in the blood, whereas in cardiac œdema the cholesterol was never increased This was confirmed in the following year by Widal, Weill and Laudat,[7] who made a careful study of the total lipoids, and found that in cases of renal disease massive albuminuria was essentially the symptom correlated with hypercholesterolæmia They noted that in these cases there was no nitrogen retention, a normal urea excretion, and no cardiovascular change, but do not appear to have laid much stress on their discovery, as they draw the conclusion that lipæmia and hypercholesterolæmia do not form so special a syndrome as chloride or nitrogen retention does In 1902 Kaiserling and Orgler[8] had shown that in certain rare specimens of kidneys seen at autopsy doubly refractive lipoids were the cause of the peculiar greasy deposits which had led to such organs being termed myelin kidneys Adami and Aschoff[9] shortly afterwards proved that such lipoids were chiefly in the nature of cholesterol esters, and Munk[10] fully recognised this type of lipoid degeneration Three examples of such kidneys have been described by McNee,[11] who in 1922 summarised the existing knowledge of the subject Further reference was made by Stewart,[12] and Parkes Weber[13] demonstrated a similar specimen at the Royal Society of Medicine in 1924 But in none of these cases was the connexion between these pathological specimens and a precedent hypercholesterolæmia referred to, save in the last, where Parkes Weber remarks "one should remember the frequency of hypercholesterolæmia in uræmic and chronic nephritic cases," showing that even at that date the connexion was imperfectly realised, the true fact being that hypercholesterolæmia is found essentially in hydropiginous and non-uræmic conditions This is brought out in the careful observations of Dyke,[14] who in 1924 published an account of six cases of dropsical renal disease in which lipoid degeneration was present in the renal tubules at autopsy. In three of these cases there were no cardiovascular changes and no nitrogen retention in the blood, and the microscopical examination of the kidneys showed considerable tubal damage with only slight changes in the glomerular and interstitial tissues In the other three cases there were, in addition to the initial œdema, hæmaturia, increased blood pressure, and uræmia at the termination, and the autopsy revealed again lipoid degeneration of the tubules but also extreme changes in the glomerular and interstitial tissues Dyke expresses the logical conclusion that the œdema in all these cases was connected with the tubal degeneration, and that the cardiovascular and uræmic manifestations were aroused by inflammatory reaction in the glomeruli, he also emphasises the view that the myelin kidney is only the extreme development of the lipoid degeneration invariably seen in the tubal tissue in cases of hydropiginous renal disease

From the conception of "nephrosis," a purely degenerative renal lesion, by Muller in 1905, the recognition of doubly refractive lipoids in the myelin kidney by Kaiserling and Orgler in 1902, and the discovery of hypercholesterolæmia in renal œdema with albuminuria by Chauffard and Widal in 1911, have arisen the modern views concerning the condition now commonly described as lipoid nephrosis These found their full expression in the work of Epstein, who in a series of papers[15] [19] published between 1912 and 1920 focussed the attention of the English-speaking world upon cases of nephritis exhibiting an enormous daily loss of albumin in the urine, a reversal of the usual albumin-globulin ratio in the plasma, with reduction of the total plasma proteins, excess of blood-cholesterol, normal blood-urea and non-protein nitrogen, and no cardiovascular changes Epstein emphasised the occurrence of apparently primary cases of this disease in young subjects, with no previous renal history, and mentions its chronic though apparently benign course, and the great benefit often observed by giving a diet rich in proteins, low in carbohydrates, and with no fat

During the same period Munk[4] had, in Germany, gradually evolved a similar conception. He describes lipoid nephrosis as an insidious disease appearing in young persons, with œdema, intense albuminuria but no hæmaturia, oliguria, normal nitrogen excretion, normal blood pressure, excess of cholesterol in the blood, and doubly refractive lipoids in the urine The course is very chronic, and on the whole benign The only difference between the description given by Epstein and that of Munk would appear to be that the former lays emphasis on the alteration in the proportions of albumin and globulin in the plasma, whilst the latter stresses the occurrence of doubly refractive lipoids in the urine

Observations on the cholesterol content of the blood in renal disease are not yet very numerous, but such as are accessible in the literature all seem to support the original observations of Chauffard and of Widal Thus, Stepp,[20] Strauss,[21] Daniels [22] Schwarz and Kohn,[23] Hiller,[24] Elwyn,[25] Kollert,[26] and Murphy and Warfield,[27] have all published confirmatory observations, whilst the negative findings of Bloor[28] are an additional confirmation in that they were made entirely upon cases without œdema It is significant to note that observations on cases of renal œdema without hypercholesterolæmia are conspicuously absent, and it seems reasonable to doubt whether such a condition can occur unless the œdema is merely due to cardiac failure following high blood pressure

Our own observations on this point agree with those referred to above, typical examples are set out in Table I

TABLE I —*Cholesterol Content of Blood expressed in Milligrammes per 100 Cubic Centimetres*

Nature of case	Cholesterol.	Nature of case	Cholesterol
Uræmia	142	Renal œdema	517
	112		444
Chronic nephritis, nitrogen retention	130		240
	140		227
	117		290

For comparison with Table I we quote from our observations on certain other cases (Table II)

TABLE II —*Cholesterol Content of Blood expressed in Milligrammes per 100 Cubic Centimetres*

Nature of case	Cholesterol.	Nature of case	Cholesterol
Pernicious anæmia	97	Obstructive jaundice	340
Diabetic coma	210		333
Cirrhosis of liver, no jaundice	131		308
Syphilitic cirrhosis, no jaundice	105		250
Addison's disease	78		305
Diabetes	127		359

Pure Lipoid Nephrosis

The summarised account of the clinical and laboratory features of lipoid nephrosis which we have given above applies to what is sometimes called its pure or primary form. How often this occurs is still a matter of considerable doubt, but cases in children and young adults are certainly not infrequent To fall into this category a case must have no history of scarlatina or other probable cause of renal inflammation, there must be albuminuria without hæmaturia from the outset, and œdema without cardiovascular change or uræmic manifestations at any time

The following case, recently observed, may be placed in this class .—

CASE 1 —W A, male, aged 22 Had suffered from measles, chicken-pox, and whooping-cough, without complications, during childhood. In 1923 had a slight attack of pleurisy In 1925 had pyodermia. In August, 1926, during a holiday, he observed that his abdomen and legs were swollen A few weeks later the face also swelled He had transitory epigastric pain and diarrhœa. Nothing abnormal was observed as to his urine Seen at the end of October, 1926, the face looked puffy The legs and lumbar region were somewhat œdematous There were ascites and evidence of bilateral hydrothorax Blood pressure 140/90, heart normal After two days in bed the blood pressure was found to be 110/70 Optic fundi normal Urine, S G 1020, eight parts of albumin per 1000, a few hyaline and granular casts No blood

Blood analysis (milligrammes per 100 cubic centimetres). urea, 30, non-protein N, 29, uric acid, 3 6, chlorides, 479; cholesterol, 209 Wassermann reaction was negative

Admitted to Middlesex Hospital under the care of Dr C E Lakin, he was put on a diet of abundant protein and no fat. The urine was found to vary between ½ and ¾ litre per diem, the albumin loss amounting to 10 g or more daily. Repeated examinations of the blood confirmed the normal nitrogen figures The cholesterol at different examinations was found to amount to 209, 256, 266, 294 mg per 100 c cm. A chloroform extract of the urine gave a faint positive reaction for cholesterol The sedimentation time of the red corpuscles was considerably diminished The basal metabolic rate was 19 per cent below normal The urea in the urine was between 2 and 3 per cent, and after the administration of 15 g of urea rose to just above 3, showing full normal concentrating power. During the first four weeks of treatment the œdema of the legs, face, and lumbar region disappeared, there was still slight ascites The daily albumin loss remained high Patient felt well. Observation continues

This case exhibits the features of pure lipoid nephrosis—namely, absence of history, oliguria profuse albuminuria, œdema, normal cardiovascular system, no nitrogen retention, hypercholesterolæmia normal concentrating power of the kidney, low basal metabolic rate diminished sedimentation time of the blood The only doubt as to the absence of other factors lies in the fact that on two occasions traces of blood were present in the urine

In addition to those of Epstein and Munk, the cases quoted by Schwarz and Kohn, Dyke, and Murphy and Warfield appear usually to have been examples of pure lipoid nephrosis The paper of Murphy and Warfield is particularly interesting in that it describes the post-mortem findings in one of these "pure" cases, the changes in the kidneys were found to be almost entirely in the epithelium of the tubules

Complicated or Secondary Lipoid Nephrosis

But there is no doubt that lipoid nephrosis is often seen in cases where there has been an initial inflammatory disease of the kidney, usually of the glomerular type And again it seems certain that many cases which are apparently a primary degeneration with characteristic albuminuria and œdema later become complicated by glomerular inflammation

The following may be given as a case falling into this class —

CASE 2 —B M, female, aged 20 Measles at age of 2 years, "nephritis" at 6, recurring at 15 She was then admitted to hospital three times, details are unknown In October, 1925, she was admitted to Middlesex Hospital under the care of Dr R A Young She had been well in the preceding March, but then began to swell in the face, abdomen, and legs Vomiting set in and had continued intermittently

On admission she had œdema, ascites, oliguria, and 20 parts of albumin per 1000 in the urine The systolic blood pressure was 140 mm, but the heart was not enlarged perceptibly Treated with a generous diet and urea administration, the œdema subsided rapidly and considerably, but on discharge she was still passing considerable amounts of albumin and the systolic blood pressure remained at 140 The urine never contained more than 1 5 per cent of urea, even after urea administration. The Wassermann reaction was negative.

Examined 13 months later, patient was at work and feeling well save for occasional headaches There was some œdema of the ankles, and she said that œdema had fluctuated considerably from month to month. Systolic blood pressure 140 mm. Considerable albuminuria

The following are the results of blood analysis at various dates —

	On admission.	Six weeks later	Eleven weeks later
Urea	32	94	58
Non-protein N	32	63	51
Chlorides	541	556	—
Cholesterol	517	240	375

The nitrogen retention and raised blood pressure in this case point to glomerular and interstitial changes of serious degree, and make the prognosis correspondingly bad The probable uræmic termination of complicated cases of this type may be illustrated as follows —

CASE 3 —E H, male, aged 16 Admitted to Middlesex Hospital May, 1923 There was no previous history save whooping-cough in infancy On admission there was œdema of legs, face, and abdomen. Massive albuminuria, hæmaturia, normal cardiovascular system Patient vomited on several occasions, but after a few weeks felt well The œdema did not subside or respond to Epstein's diet During the following months the œdema fluctuated, albumin passed amounted to from 8 to 20 parts per 1000 Headaches occurred, there was a steady increase in blood pressure, and nitrogen retention in the blood became evident At the beginning of September, after a single convulsion, the patient became suddenly comatose and failed to recover consciousness, in spite of hot-air baths, venesection, and lumbar puncture He died in 36 hours

	May	June	July	August	Sept	P M *
Systolic b p	125	148	144	160–176	200	—
Blood-urea	28	55	55	—	—	54
Non protein N	27	49	45	—	—	73

* Post mortem

The total albumin lost per diem appeared to bear some relation to the patient's general condition, being markedly increased during the final week

Elwyn, whose recent paper is an important one, admits the occurrence of pure lipoid nephrosis, but appears to stress the frequency with which the disease is really secondary to an inflammation affecting the glomerular epithelium, and it is noteworthy that in the cases of Dyke there were always histological changes in the glomeruli, although these were far more conspicuous in those examples which had later developed high blood pressure and uræmia. It is certainly difficult to explain albuminuria of the massive type seen in these cases on any hypothesis save that of increased permeability of the glomerular epithelium, but it should be added that such increased permeability does not necessarily imply an inflammatory lesion The occurrence of lipoid nephrosis secondary to an initial nephritis is, however, not questioned It may here be recalled that in the early observations of Widal, Weill and Laudat several of the cases exhibiting œdema and hypercholesterolæmia were examples of tuberculous disease of the kidney

Treatment of Lipoid Nephrosis

Much of the interest aroused by the original publications of Epstein was due to the line of treatment of cases of chronic renal œdema there suggested References in English literature by Galloway,[29] and by MacLean and de Wesselow,[30] dealt almost exclusively with this side of his work, the possibility of dietetic replacement of albumin lost in the urine being the factor which aroused attention rather than the correlation of the cholesterol excess, this latter factor being apparently little considered Epstein's diet consists essentially in the replacement of carbohydrate as far as possible by protein and an entire elimination of fats

In common with many other observers, we have seen occasional brilliant effects from this treatment, but it is generally agreed to-day that there is no uniformity in results, which are often disappointing, the first case we have quoted in detail showed great benefit, the second also exhibited great temporary relief in the degree of œdema, the third failed entirely to respond In the last case this was probably due to the progress of glomerular change and nitrogen retention, but it must in general be admitted to day that Epstein's diet is uncertain in its effects, although it has shown the frequent advantage of a generous diet in cases without signs of nitrogen retention

A further interesting form of therapy in cases of lipoid nephrosis is the administration of thyroid extract. Eppinger[31] has shown that a lowered basal metabolism is frequent in this disorder, and considerable benefit is sometimes observed as the result of giving thyroid extract The high doses tolerated by most patients is indirect evidence in favour of such treatment

The administration of urea by mouth appears to be rational if *blood analysis at repeated* intervals shows that there is no nitrogen retention.

Some Unsolved Problems

In the space of the present paper it is impossible to deal adequately with the many important problems that arise from consideration of the phenomena of lipoid nephrosis

The mechanism of the œdema is, perhaps, the chief of these Abandoning the classical theory of salt retention, Epstein has endeavoured to explain this on the basis that the profuse albuminuria causes such loss of plasma albumin that water is drawn from the blood stream to the tissues by the force of osmosis. Elwyn has more recently put forward the view that the body endeavours to check the albumin-loss in the urine by diminishing the urinary flow, and that the consequent tendency to an increased blood volume is then corrected by the passage of water into the tissues; this ingenious hypothesis seems to lack experimental support

The second outstanding problem is the significance of the hypercholesterolæmia Does it appear from the outset, or is it only apparent after albuminuria and œdema have been prominent for some time? Of its intensity there seems to be no question, indeed our personal observations and those of many others who have inquired into the subject seem to point to the cholesterol excess in lipoid nephrosis being greater than in any other common disease save possibly obstructive jaundice In a few cases of transient œdema of renal origin in gravid women we have found a blood cholesterol within the high limits usually observed in pregnancy, but we have not been able to trace record of any cases of chronic œdema in renal disease, apart from cardiac failure, in which a normal or low blood-cholesterol has been found after repeated examination

The prognosis in these cases is a further obscure point A certain number appear to make a rapid and complete recovery, but the vast majority become chronic, although the œdema appears to wax and wane considerably Their very chronicity is the chief reason why complete records are relatively scarce, the general hospitals are unable to house them indefinitely, and they pass out of observation A considerable number become complicated by nephritis and die in the typical manner of renal failure, in uræmic coma But many others appear to terminate with a low-grade peritonitis which certain German authorities believe to be pneumococcal

Lastly, a word must be said concerning the macroscopic appearance of the kidneys in these cases Is it not time that the story of the large white man with the large white kidneys were abandoned? There is no uniformity in the naked-eye appearance of the kidneys seen in autopsies on patients dying with lipoid nephrosis, but it seems certain that kidneys which are large and white are somewhat unusual The matter is, perhaps, unimportant, but we mention it because it has for years distracted attention from the findings of the laboratory and the microscope, which are probably of much greater import to the clinician

We wish to express our thanks to Dr Young and Dr Lakin for permission to publish certain observations on cases under their care Expenses incurred in this inquiry were partially defrayed by a Government grant made on the recommendation of the Royal Society This paper forms part of a report to the Medical Research Council

Summary

1 Apart from albuminuria, it is difficult to demonstrate any clinical evidence of renal disorder in the dropsical type of "nephritis"

2 On account of the paucity of clinical and microscopical evidence of inflammation in many of these cases they are frequently spoken of as examples of "nephrosis" rather than "nephritis"

3 Hypercholesterolæmia has been shown to be a conspicuous feature of these cases, in sharp contrast to those with uræmia and cardiovascular changes, where the cholesterol content of the blood is usually normal

4 The "myelin kidney" is probably the extreme development of the common anatomical change in this condition, which in milder cases exhibits itself merely as lipoid degeneration of the renal tubules

5 Examples are given of the cholesterol content of blood from these and other diseases

6 Cases are detailed (*a*) in which there was apparently pure lipoid nephrosis, and (*b*) in which this condition was complicated by nephritis, nitrogen etention, and uræmia

7 The most promising treatment at present is by the "Epstein" diet and thyroid administration

8 The mechanism of the œdema and the significance of the hypercholesterolæmia in these cases cannot at present be explained

9 These cases are almost invariably chronic, death is usually due either to a low-grade peritonitis or to uræmia as a complication.

10 The "large white kidney" is not a common finding at autopsy.

SERUM PROPHYLAXIS IN MEASLES

AN EVALUATION OF THE RESULTING IMMUNITY

By A. NEAVE KINGSBURY, M B, B S Lond, D T M & H,

PROFESSOR OF BACTERIOLOGY, KING EDWARD VII COLLEGE OF MEDICINE, SINGAPORE.

(*From the Institute for Medical Research, Kuala Lumpur*)

THE writer has recently attempted the control of an epidemic of measles on rubber estates in the Federated Malay States by inoculation of the children *en masse* with serum from convalescent cases A description of the method employed and a critical survey of the immediate results will, in due course, be communicated to the medical press But some months after a number of plantation outbreaks had thus been brought to a close morbilli reappeared on three of the seven estates on which serum prophylaxis had been practised Comparatively little is yet known of the degree and duration of the passive immunity conferred by this mode of protection, and it is therefore proposed to record some observations on these points in the present paper.

Immediate Results of Serum Prophylaxis

The immediate results achieved with 395 children are summarised below Groups numbering 93, 132. 50 and 120 children were given 2, 2 5, 3, and 3 5 c cm of serum respectively During the seven weeks following inoculation the incidence in these groups was 15 per cent, 4 5 per cent, 14 per cent and 1 per cent Cases continued among adults and uninoculated children after the last cases in the inoculated groups on all the estates, so that opportunity for infection was not lacking. Yet there were not more than 28 cases among the 395 children, and only six of these developed the rash after an interval of ten days had elapsed from the date of inoculation. The average incubation period may be taken as ten days, and the rash of measles usually appears on about the fourteenth day after infection, but when serum is given, many instances have been recorded in which the incubation period has been considerably lengthened If this factor be ignored, 22 of the failures probably received serum on or after the fifth day of incubation and when serum was given in doses varying from 2 to 3 5 c cm before exposure or during the first four days of incubation the failures were only 1 6 per cent.

Duration of Passive Immunity

A period of from one to three months has been cited by various investigators as the duration of the transient immunity which follows the inoculation of convalescent serum McNeal (1922) has reported an infection two months after protection, and v. Toobay (1921) three cases between the seventy-second and seventy-fifth day Duration will necessarily depend on antibody content and dosage of the serum, but the following instances which have occurred in the writer's series indicate that immunity may continue for considerably longer periods —

1 During the first week of November, 1925, 93 children belonging to estate No 1 were inoculated with 2 c cm of plasma from convalescent cases Fourteen of these developed measles, the last case occurring on Nov 19th, though cases continued among the adult coolies until Nov 27th In a small control group of ten uninoculated children on this estate eight became infected. Thus 79 inoculated and two uninoculated children escaped On March 31st, 1926, two new coolies from India arrived on the estate They had been quarantined for cholera at the F M S Quarantine Station before admission to the country, but it is the practice of the estate medical officer to isolate all new coolies on the estate for an additional six days when there is a history of recent contact with cholera cases These men were not therefore allowed in the coolie lines until April 6th They then mixed freely with the estate coolies and children and on the afternoon of April 8th both were admitted to hospital with typical measles eruptions In both instances the disease ran a mild course. All the estate children were examined for measles daily until April 23rd, but no fresh cases were reported, although the inoculations had been done some five months previously.

2 On Division A of estate No 3, 62 children were inoculated with 2 5 c cm. of serum on Nov 14th, 1925, 16 being kept as controls During the three weeks following there were five cases among the inoculated children and three in the control group The numbers of inoculated and control children who escaped were therefore 57 and 13 respectively On March 11th, 1926, measles reappeared among the adult coolies of the division, and up to April 20th this secondary outbreak involved 13 cases, including three (5 per cent) in the inoculated group and two (15 per cent.) among the controls The cases were all of a mild nature It thus appears that some residual protection was operative in a percentage of the children four and a half months after inoculation.

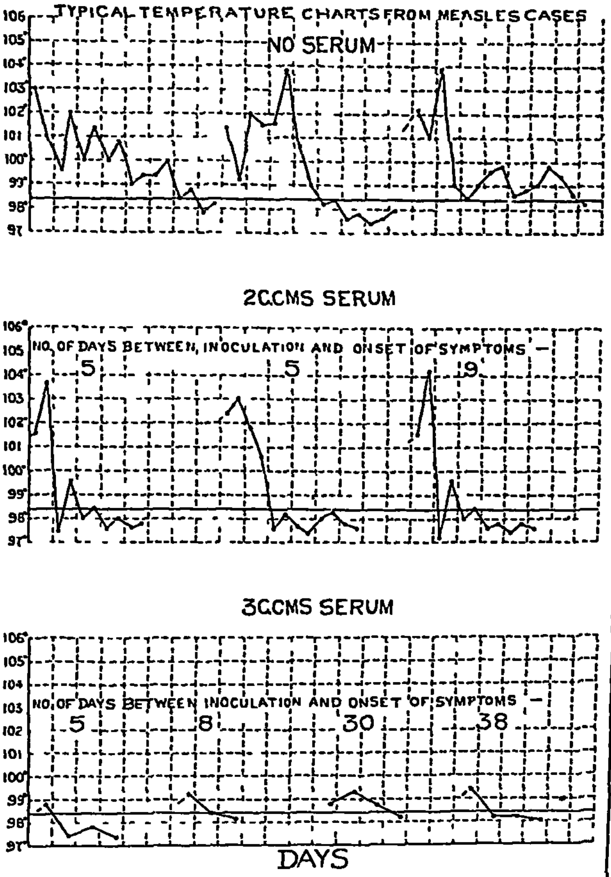
3 A secondary outbreak of measles also occurred on estate No 6, but in this instance the writer can only quote hearsay evidence, as he had, in the meantime, been transferred to Singapore. The inoculation of 75 out of 107 children on Dec 26th, 1925, with 3 5 c cm. of serum was followed by one further case in each group Cases in the following June numbered about 20, but only one or two of the inoculated children are said to have become infected

Attenuated Measles

The introduction of serum prophylaxis was followed by the observation of a striking modification in the course of the disease when such treatment was given in the later stages of incubation. Under these circumstances the malady is not aborted, but the incubation period may be increased, and the character of the disease is rendered so mild that complications and serious sequelæ are but rarely seen. Attenuation has also been noted in the few instances of the present series where serum, although given some time before infection, failed to protect, and the rash developed three weeks or more after inoculation

Of the 28 cases which developed measles within seven weeks of treatment, all but one of the children had very mild attacks The exception was a child aged 3 years, on whom the rash appeared seven days after the injection of 2 c cm of plasma Bronchopneumonia supervened, but the course was comparatively benign, and the little patient was discharged from hospital 14 days after admission A contributing cause of this complication was probably the migration of ascaris larvæ through the lungs On two control estates 13 children had serious complications, and six died among 69 cases

The cases of modified measles observed by the writer have been characterised by a comparative absence of catarrhal symptoms This probably greatly reduces the infectiousness of such cases The rash has been faint, with individual macules almost discrete, and the abbreviation in the course is well illustrated by the temperature charts reproduced on the accompanying figure Records are only available from the time of the onset of the rash, as the coolies ignore symptoms of invasion, and only report sick on the appearance of the eruption The upper part of the figure shows three charts typical of the febrile course in a large number of untreated children Beneath this are three charts from children who had been inoculated with 2 c cm of plasma, and developed the rash 5, 5 and 9 days afterwards The initial temperatures of these cases were as high as those of the controls, but defervescence was complete by the third day Four temperature charts are given on the bottom of the figure from children who received 3 c cm of serum and had symptoms of measles 5, 8, 30, and 38 days later The maximum temperature noted in this group was 99 9° F and by the second day all the cases had become normal



This attenuation of the disease following serum administration may be employed as a basis for estimating residual protection in cases which develop measles some months after inoculation Reference has already been made to the secondary outbreak which occurred on Division B of estate No 3, four and a half months after the majority of the children had been protected All the cases were very mild but the difference in the temperatures is seen below —

—	Case No	Age (in years)	Rash appeared on	Maximum temperature	
				First day	Second day
Inoculated children	1	2½	26/3/26	98 6° F	Normal
	2	9	1/4/26	98 6° F	"
	3	1	16/4/26	98 4° F	"
Controls	1	2	27/3/26	100° F	Normal
	2	1½	1/4/26	99 8° F	99·0° F

The initial temperature in the two controls was thus over a degree higher than in the three inoculated children and this fact, taken in conjunction with the higher incidence among the control cases, indicates that a degree of immunity was still operative

Commentary

In areas where measles appears from time to time in epidemic form, inoculation of the children with convalescent serum is a useful method for controlling the disease This is particularly the case when the population is grouped in small communities as on plantations or in villages With a dosage of 3 5 c cm of serum, a large percentage is protected, and, if measles supervene, the disease is attenuated even after an interval of four and a half months has elapsed.

But for endemic areas such as Europe and North America, this prophylactic measure cannot be considered suitable Immunity transmitted from mother to offspring disappears between the sixth and twelfth months of life, and some 80 per cent of the deaths from measles occur during the first four years. Protection which does not endure for about four years cannot, therefore, be of great value under urban conditions where opportunity for infection is almost continuous This period can only be covered by the conferring of an active immunity

The problem is immensely important in these days of falling birth-rates, for the annual death roll from measles approximates to 100,000 in European countries Bernard (1925) has observed that the mortality-rate is falling less rapidly than for scarlet fever and whooping-cough Little improvement can therefore be anticipated in this appalling loss of infant life until effective prophylaxis is actively employed A method which will protect during the first four years of life could save some 80,000 lives anually in Europe alone

Débré and Ravina (1923) have introduced an ingenious means of established active immunity They inject convalescent serum during the later stages of incubation thus causing attenuation of the disease The consequent comparative absence of coryza renders such cases much less dangerous to the child community, while the resulting immunity should endure throughout the danger period of early life But the coryza of the invasion period or the onset of the rash is only too frequently the first intimation of infection It is in a very small number of cases that the date of exposure is known, and injections can be given at the critical time

In the opinion of the writer a temporary solution of this problem in immunisation for endemic areas has been found by Nicolle and Conseil (1923) These workers suggested that active immunity could be best achieved by the use of convalescent serum followed 24 hours later by a small injection of blood from an acute measles case Experimental work should be directed to the determination of the optimum dosage of serum and virus, but when the day arrives that the measles virus can be cultured with certainty, the method will probably give place to a single inoculation of virus and artificially prepared immune serum

A CASE OF
OSTEOGENESIS IMPERFECTA

By DONALD HUNTER, M D , M R C P. Lond ,
MEDICAL FIRST ASSISTANT, LONDON HOSPITAL

(With Coloured Plate)

The purpose of this communication is, first, to record an interesting case, and, secondly, to urge the necessity of full chemical and pathological investigations into similar cases in view of the discovery that potent extracts of bovine parathyroids cause considerable excretion of calcium from the bones

Clinical History

T G S a youth aged 17 There was no history of fractures, blue sclerotics, deafness, nor a peculiar shape of the head in grandparents, parents, or brothers and sisters The patient is the ninth of 11 children Three of these died as babies either of pneumonia or in convulsions The mother had two miscarriages

He was a full-term baby and the labour was easy At birth he weighed 8 lb and was a " fine, healthy baby " with no deformity of any sort The blue sclerotics were noticed a few days after birth He was breast-fed until nine months and was then given Nestle's milk and barley water At 12 months he was given crusts, and subsequently a similar diet to the rest of the family He had his first tooth at 9 months, and began to talk at 18 months He did not crawl as a baby and has never walked The " opening in the head " closed between the third and fourth year He had measles and chicken-pox as a child, but otherwise, except for fractures and dislocations, he has been " very healthy " The second dentition began to appear at 10 years He attended an L C.C special school for cripples from the age of 10 to 17. He learned to read and write quite well He can stand only if he holds on to something, and even then he is very unsteady He slides about the house on his buttocks, and gets upstairs on his hands and knees

History of Special Condition

1 At birth there were no fractures and, as far as can be ascertained, the head was normal

2 At three weeks the right humerus was fractured while the mother was lifting him from his bath It was placed in splints and apparently united well in a few weeks

3 At 5 months he was admitted to the London Hospital under the care of Mr P Furnivall His brother had slipped while carrying him and had broken his left femur without actually dropping him The fracture united after treatment for three weeks in a gallows splint

4 Between 18 months and 2 years " the left leg was broken three times " These fractures were treated at home by the application of bandages

5 At 3 years he was again admitted to the London Hospital under the care of Mr P Furnivall, when the diagnosis " osteogenesis imperfecta " was made Apparently he had been sent to a home in the country where, according to the mother, " the nurses were very careless and broke three of his bones " He had subperiosteal fractures of the right femur, right humerus, and right ulna An interesting statement appears in the house surgeon's notes that " the head is hydrocephalic and the anterior fontanelle admits the little finger " The Wassermann reaction was negative " The bones united soundly " after immobilisation for six weeks

6 At 6 years he was admitted to the London Hospital under the care of Mr T H. Openshaw He then had a subperiosteal fracture of the right femur which united in two weeks

7 At 11 years he was admitted to the Mile End Hospital with a fracture of the right forearm

8 At 13 years he " put out the left shoulder " From his own description there is little doubt that this was a dislocation of the joint

9 He states that at 14 years some one fell over him in the dark and " put out both hips and the right collar bone." From his description it seems likely that he dislocated the left hip, but fractured the right femur and the right clavicle Following this accident he was in bed for three months

10 At 17 years he was twice admitted to the Mile End Hospital under the care of Dr J I P Wilson and Dr C D Coyle, who kindly gave me permission to transfer him to the London Hospital On the first occasion, according to the mother, " he was trying to stand in the garden when the wind blew him down " He fell on his outstretched hand and broke his left forearm in three places On the second occasion he caught his left foot under a chair and, in attempting to withdraw it, fractured the left femur The left thigh was placed between sand-bags, and the fracture united in five weeks After admission to the London Hospital, while raising himself in bed on the outstretched left hand, he broke the left radius This was a subperiosteal fracture associated with little pain and no displacement.

It is difficult to obtain exact information as to the total number of fractures The mother thinks he has broken his bones " more than 30 times " The bones of the right arm and leg have been more often fractured than those of the left In his early childhood he was much more liable to fractures than later, and the mother states that " at one time when you lifted him you could hear his bones crack and he would cry out with pain " Since the age of 10 years he has fractured his bones much less frequently. With the exception of two falls on the face, in which he broke his nose, the fractures have been produced without violence. They often occur " when his brothers are a little rough with him " Pain is certainly associated with the fractures, but it is neither severe nor prolonged The information with regard to dislocations is less trustworthy but apparently " five or six " dislocations, usually involving the right shoulder but sometimes the left hip, have occurred

Examination —A slightly pale, ill-nourished dwarfed, deformed boy of normal intelligence His total height is less than two-thirds that of a normal control He is unable to walk and stands only with difficulty

Table Showing Weight and Measurements

	Patient		Control of same age
Weight in kilogrammes	24 4		61
Pelvimeter measurements, in cms —			
Biparietal diameter	14		15
Diameter 1 cm in front of ears and 4 cm below parietal eminence	*15 5*		14 5
Occipito frontal diameter	*20*		18 5
Root of nose to base of occiput	15		17
Between malar bones	10 5		11 5
Root of nose to tip of chin, with mouth closed	10		11·5
Intercristal diameter	21		26 5
Measurements by tape measure in cms —			
Total height	105		170
Sitting height	52		82
Circumference of head			
At parietal eminences	*55*		54 5
Just above ears	*50*		53 5
Through root of nose and occipital protuberance	*57*		54
Circumference of chest at nipple line	69		88
Circumference of abdomen at umbilicus	61		68
Circumference of neck	26 5		34
	Right	Left	
Length of upper limb	55	61	76
„ upper arm	21	25 5	30
„ forearm	19	20 5	25
„ hand	15		21
„ lower limb	62	68 5	104
„ thigh	25	33	47
„ leg below knee	21 5	24	37
„ foot	17		25

Skull —The vault of the skull is flattened as if from a weight applied above The occipital bone makes an angular protrusion which is continued forwards, making a wide horizontal ridge from ear to ear There is bilateral temporo-parietal protrusion of the skull, very evident on the right side. This supra-aural enlargement bends the right ear, and to a less extent the left, outward and downward There is no abnormal protrusion of the frontal region The deformity of the skull is so extreme that, whereas every other measurement in the body is much less than that of a control, the bi-temporal and occipito-frontal diameters, together with the corresponding circumference, are actually much greater The bones of the skull appear firm and of normal thickness, the fontanelles are closed, no sutures are palpable, and no craniotabes is found

Jaws and Teeth —There is slight protrusion of the lower jaw so that the lower teeth are opposite the upper Owing to deformity of the lower jaw there remains a slight gap between the incisor teeth when the molars meet. The teeth are regularly spaced and, except for two carious molars, they are sound

Eyes —The orbits are shallow, giving prominence to the eyes Their horizontal axes slope downwards and outwards so that the outer canthus of the eye, especially on the right side, is lower than the inner canthus The sclerotics are a uniform grey-blue of moderate intensity The irides are ill-formed, with poor striation and a dull grey colour The fundi are normal

Face and Neck —The face is flat, though the bridge of the nose is well formed There is some degree of asymmetry owing to mal-union of the nasal septum, from which a spur of cartilage projects into and partly obliterates the left nostril There is scanty hair on the upper lip, but none on the face The neck is short The thyroid gland is normal in size and consistency

Nervous System negative There is no defect of hearing

Spine —There is severe lower dorsal scoliosis with the convexity to the right He can sit up without difficulty, but the sitting height is little more than half the normal

Thorax —The thorax is short and broad There is considerable deformity of the sternum and ribs , a broad, triangular, beak-like projection of the chest wall, commencing at the level of the nipples, protrudes downwards and slightly forwards over the epigastrium The apex of this projection is formed by a buckling of the sternum at the level of the fifth costal cartilage There is no enlargement of the costochondral junctions Axillary hair is absent

Heart and Lungs negative No change is detected in the arteries The blood pressure is 135/95 mm Hg

Abdomen —The abdomen is normal in contour No abnormality is detected on palpation The external genital organs are well developed the pubic hair is normal

Extremities —All four limbs are deformed, the right being more affected and shorter in length than the left The thighs, forearms, and right tibia show anterior bowing There is outward twisting of the shafts of the long bones of the lower limbs, so that the feet are extremely everted Angular deformities and palpable callus are absent There is no enlargement of the ends of the long bones The proximal bones of the right upper and lower limbs are disproportionately short compared to the distal bones, there is no such disproportion on the left side There is some limitation of extension of both elbow-joints, worse on the right side Elsewhere the joint ligaments are lax, so that the range of movement of the shoulders, hips, wrists, and ankles is abnormally wide The muscles are hypotonic The hands and feet are short but are not otherwise deformed (For clinical discussion see Bronson[1])

Urine normal

Blood Count —Red cell count, 1,900,000, hæmoglobin, 75 per cent , colour-index, 0 7, white cell count, 5240, polymorphs, 60 per cent , eosinophils, 1 5 per cent , small lymphocytes, 27 per cent , large lymphocytes, 8 5 per cent , large hyaline cells, 2 5 per cent , basophil cells, 0 5 per cent

Wassermann Reaction in Blood negative

Blood-urea, 0 030 per cent

Glucose-tolerance Test —Fasting blood-sugar=0 091 per cent 50 g glucose by mouth Blood-sugar, after 45 minutes, 0 105 per cent , after two hours, 0 083 per cent

Serum Calcium, 10 3 mg per 100 c cm

Inorganic Phosphate in Serum, 3 8 mg per 100 c cm

Calcium Output —The calcium output was estimated in the urine and fæces over a period of nine days, during which the patient was kept on a weighed diet of known low calcium content The energy value of this diet was 1150 calories daily During the nine days distilled water was used in the preparation of all his food and drinks The fæces were divided into three-day periods by the oral administration of 0 3 g of carmine alum lake every third day The urine was obtained in 24-hour specimens I am indebted to Dr P Morton for some of the analyses The record of the calcium exchange is tabulated below, the figures being milligrammes of Ca per three-day period

Record of Calcium Exchange

Three-day period	Intake	Output			Balance	
		Fæces	Urine	Total		
			Patient			
	mg					
I	153	283	349	632	−479	
II	153	183	293	476	−323	Average −269 mg
III	148	122	240	362	−214	
			Control			
I	132	248	110	360	−226	
II	95	352	37	389	−294	Average −256 mg
III	268	444	41	485	−217	
IV	251	207	170	377	−126	
V	256	369	190	559	−303	
VI	278	508	110	618	−340	

The control was a male patient of 19, weighing 61 8 kg and observed under similar conditions as to diet

On such a low calcium intake there is, of course, a negative calcium balance Discarding Period I in both patient and control, it is found that the calcium balance is similar in both cases (patient −269 mg, control −256 mg) It is realised that there may be fallacies in the experiment, since on the one hand the calcium intake was so inadequate, and on the other the dwarfing of the patient made it very difficult to devise satisfactory control observations

Radiological Report

I am indebted to Dr M H Jupe for the radiograms and for the following report

Skull —The vault appears too large in proportion to the bones of the face The distance between the tables is reduced so that the bones appear thinner than normal This is especially noticeable from the bregma to the region of the lambda at which point there is an angular projection From here the occiput sags downwards considerably There is also loss of prominence in the frontal region of the skull The structures forming the base of the skull appear to be flattened in their vertical dimension This probably accounts for the lack of prominence of the mastoid shadows, and for the slight shallowness of the sella turcica which in other respects appears normal

Long Bones —All the long bones show shortening and bowing The shadows of the bones are hardly more dense than those of the surrounding soft tissues There is very great thinning of the cortex, more noticeable on the convex side The spongiosa both of diaphyses and epiphyses is extremely faint, so that in places the normal pattern cannot be discovered The epiphyseal lines appear normal There is very little evidence to indicate the sites of the old fractures However, in the region of the lesser trochanter of the right femur there are two fine transverse lines of comparative sclerosis running parallel There is nowhere evidence of the formation of callus nor of periosteal new bone There is no suggestion of cyst formation

Ætiology

There have been almost as many theories to explain the process at work in the bones as there have been observations Many of these are based on histological evidence Most authors have found a decrease in the osteoblasts with defective production of osteoid tissue [2] [3] Schuchardt [4] postulated defective periosteal ossification (periosteal dysplasia) to explain the thinning of the corticalis Scheib [5] and Harbitz [6] thought that there was both excessive resorption of bone and halisteresis Most authors agree that the epiphyseal cartilages are normal Bauer [2] claimed that the calcification of cartilage and of osteoid tissue was normal as seen in histological sections Harbitz,[6] however, thought the zone of provisional calcification abnormally thin and in places absent

None of these suggestions bears on the underlying cause of the disease Bauer [2] suggested deficiency or lowered vitality of all tissues of mesoblastic origin and showed histological abnormalities in bone, cartilage, and tooth pulp Jansen,[7] on the other hand, suggested an embryonic defect due to abnormal amniotic pressure

The glands of internal secretion have been suspected. Nicklas [8] and Bauer [2] both report cases with congenital goitre found at autopsy However, it is open to question whether the fœtal thyroid functions, and hence whether it can cause a disease which begins in utero Meissner [9] described two cases in young girls, one with premature and the other with abnormal sexual development The findings of Malcolm [10] that, in dogs, administration of fresh pituitary substance by mouth caused an increased output of calcium, led Klose [11] to suspect the pituitary There are two cases recorded which show definite enlargement of the parathyroids The seven-months fœtus described by Bauer [2] had four enlarged parathyroids, the largest the size of the adult gland (3 mm diameter) Histologically these showed hyperplasia He relates that Dietrich [12] described another case

Chemical Findings

Observations on the inorganic constituents of the bones are scarce In 1857 Barker [13] found that the bones in a congenital case yielded 33 3 per cent of ash, while Regnard, quoted by Enderlen,[14] found

Plate showing blue sclerotics.

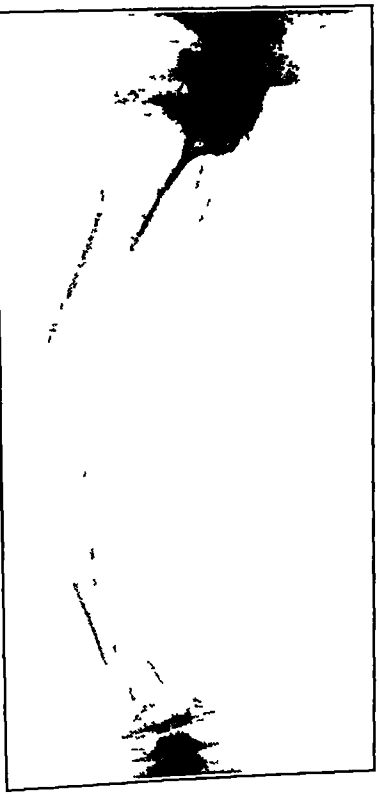
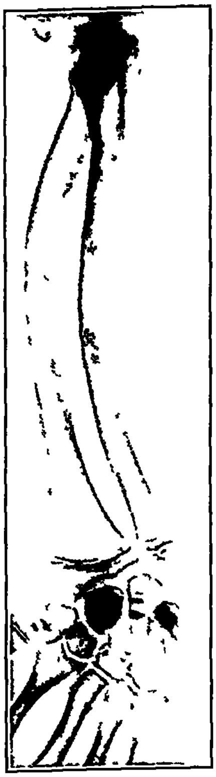
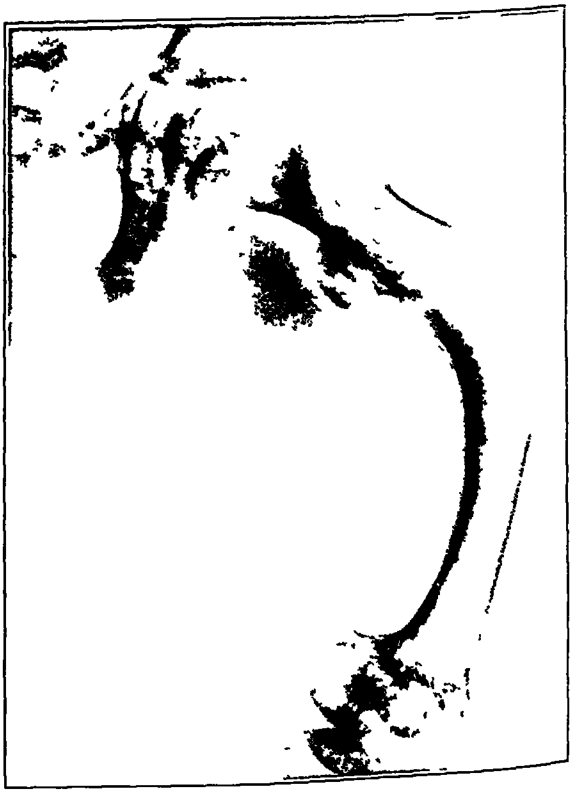
Osteogenesis Imperfecta Radiogram of Skull.



Tibia and Fibula



Radius and Ulna



Hip-joint and Femur

24 per cent. of ash. Normal bones examined by Enderlen yielded 68·5 per cent. of ash.

The blood calcium and phosphorus were determined by Flagstad, Zanger, and Leven [15] in three cases and found to be normal. In the case here recorded the findings were normal. Schwarz and Bass [16] and Bookman [17] found calcium retention slightly decreased in cases of the congenital type of the disease. From observations on a child of 7 lasting over more than two years Schabad [18] concluded that there was increased loss of calcium and a corresponding loss of phosphorus in osteogenesis imperfecta.

In the case here recorded there was no increased loss of calcium compared to a normal control. However, our patient is ten years older than the oldest case described above, and it is conceivable that as the tendency to fractures becomes less the calcium exchange becomes more nearly normal. There is a large and increasing amount of evidence that further investigations of the blood chemistry, metabolism, and morbid anatomy of this disease, and especially of the younger cases, may be rewarded with some success. This evidence concerns the function of the parathyroid glands and is partly physiological and partly pathological.

Physiological Considerations.

The exact mode of action of the parathyroid hormone is unknown. However, it has been established in dogs and in man that active extracts of the parathyroid glands cause considerable excretion of calcium from the bones.

The pioneer work was done by MacCallum and Voegtlin,[19] who found a reduced calcium content in the blood-serum of dogs after parathyroidectomy. This observation has since been abundantly confirmed, but their statement that such dogs showed an increased excretion of calcium has not been corroborated. Thus arose the erroneous idea, to which Salvesen [20] later contributed, that parathyroidectomy was associated with a lowered threshold for the excretion of calcium by the intestines. It was supposed that the resulting drain on calcium kept the blood-serum calcium at a low level. Greenwald and Gross [21] [22] have demonstrated that the true conception of the relation of the parathyroid glands to calcium excretion is the very reverse of that stated above, for their dogs after parathyroidectomy actually showed a *decrease* in the excretion of calcium. A direct means of settling this vexed question appeared when the work of Hanson,[23] Berman,[24] Collip,[25] and Hjort, Robison, and Tendick [26] made available a potent extract of bovine parathyroids.

Thus, in a further series of experiments, Greenwald and Gross [22] injected normal dogs with Collip's parathyroid extract and found that the increased concentration of calcium brought about in the blood-serum was followed by an *increase* in the excretion of calcium in the urine and fæces. Similarly, during certain investigations on lead poisoning Hunter and Aub [27] showed that, in five patients out of six, Collip's parathyroid extract (Eli Lilly) caused marked elevation in the blood calcium. In all six patients calcium excretion in the urine and fæces was very considerably increased. Thus, in the accompanying chart is shown a metabolism experiment on one of our patients extending over a period of six weeks. Collip's parathyroid extract was given by intramuscular injection in increasing doses and the blood calcium was thereby raised from 9·5 to 14 mg. per 100 c.cm. The effect of the calcium output can be judged from the chart. In the urine this was increased from 0·05 g. to 0·75 g. per three-day period. Though the effect was less marked in the case of the fæcal output, the total result was to increase the negative calcium balance *three-fold*.

We maintain, as, indeed, did Greenwald and Gross in dogs, that this increased calcium excretion occurs at the expense of skeletal deposits of calcium.

Pathological Considerations.

The physiological observations quoted above gain in interest when we consider the large number of cases reported in the literature where parathyroid tumours are associated with one or other of the so-called "malacic diseases" of bone. Erdheim [28] was the first to point out enlarged parathyroids in cases of osteomalacia. Hoffheinz,[29] rejecting all cases where the enlargement of the parathyroids was indefinite or inadequately described, collected from the literature 45 cases with *measurable* enlargement of one or more parathyroids. Of these 27 were associated with definite bone disease, including 17 of osteitis fibrosa, eight of osteomalacia, and two of rickets. Sometimes more than one parathyroid gland was affected. He quoted increases in size up to 4·5 by 2·1 by 1·2 cm. The histological change was usually a hyperplasia. Dawson and Struthers [30] have described a case of osteitis fibrosa with a parathyroid tumour the "size of a walnut." Gödel [31] has published a case with the clinical appearances of osteitis fibrosa, in which at a partial autopsy he found two parathyroid tumours, one measuring 10 by 2 cm., and the other 5·4 cm. diameter. Lastly, Mandl [32] published a case of osteitis fibrosa in which the daily excretion of calcium in the urine was 54 mg. Removal of a parathyroid tumour (2·5 by 1·5 by 1·2 cm.), which Erdheim and Maresch thought was probably malignant, was followed by a fall in the daily excretion of calcium in the urine to 7·6 mg., and by improvement of the clinical condition. The blood calcium was not estimated before operation (personal communication).

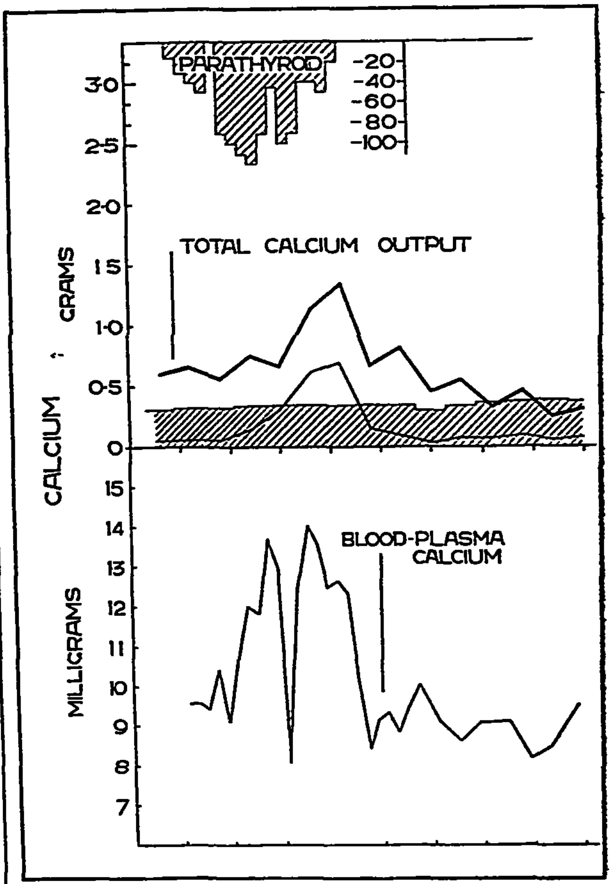


Chart showing the effect of parathyroid extract on the blood calcium and on the calcium excretion.

The interval marks on the abscissa represent five days.

In the upper portion of the chart the upper block represents treatment with parathyroid, the adjacent scale indicating units per day. The lower blocks represent the calcium intake in three-day periods. The faint line represents the excretion of calcium in the urine expressed in output for three days. The heavy line is the total excretion of calcium in urine and fæces for three-day periods. The distance between heavy line and blocks, therefore, represents the positive or negative calcium balance.

In the lower portion of the chart is shown the blood-plasma calcium.

Without further evidence it is unjustifiable to assume that these tumours are primarily responsible for the changes in the bones However, the possible occurrence of parathyroid hyperfunction must be borne in mind and investigators should endeavour to elucidate this point

In order to do this we would suggest the following investigations in all suitable cases (1) Estimation of the calcium and inorganic phosphate in the blood-serum (2) Estimation of the total output of calcium and phosphate in a series of controlled periods where the intake is known accurately (3) In autopsies the anatomical and histological examination of the glands of internal secretion paying special attention to the parathyroids

Summary

A case is recorded of osteogenesis imperfecta associated with blue sclerotics The family history is negative Corresponding to the early onset at three weeks there is dwarfism and deformity of the skull The long bones have been fractured at least 30 times without violence, the left tibia alone escaping Radiograms show the classical shape of the skull, the long bones are short and bowed and show an extremely thin corticalis and faint spongiosa The blood-serum calcium and inorganic phosphate are normal The total excretion of calcium on a known low calcium diet is the same as in a normal control The effect of Collip's parathyroid extract in raising the blood calcium at the expense of skeletal calcium is discussed Reasons are given in support of a more complete inquiry into the calcium and phosphorus metabolism in cases not only of osteogenesis imperfecta but also of osteitis fibrosa

My thanks are due to Lord Dawson for allowing me to investigate and to publish this case, to Mr W T Shiells for the drawings, and to Mr H J Suggars for the prints of radiograms

GASTRO-DUODENOSTOMY

FURTHER EXPERIENCES

BY E R FLINT, F R C S ENG,
ASSISTANT SURGEON, GENERAL INFIRMARY, LEEDS

IN THE LANCET (1923, ii 508) I reported a series of 53 cases of chronic duodenal ulcer, in 50 of which I had done gastro-duodenostomy, in the other three I did posterior gastro-enterostomy, in two, owing to dense adhesions, and in the other because a large inflammatory mass around the ulcer made it unwise, in my opinion, to attempt the former operation I have continued practising the operation, and now wish to report a series of close on 200 cases

Points in Technique

I repeat that it is quite easy to mobilise the duodenum in practically every case In the last series I have done gastro-enterostomy in six cases, twice because the pancreas completely surrounded the second part of the duodenum, twice owing to extensive adhesions, and twice because I had to remove the gall-bladder at the same time and was afraid the gastro-duodenostomy anastomosis might be caught up in the scar of the gall-bladder bed In all the other cases mobilisation of the duodenum was easily accomplished

One detail in the technique I believe to be important and that is to free the angle between the second and third parts of the duodenum, where it turns to the left to cross the spine, it is better to free this end of the second part rather than the upper angle where the first and second parts meet as at this point there are often very embarrassing vessels

As for the rest of the technique, it is much the same as that of gastro-enterostomy, except I do not use a clamp on the duodenum, and I do not stitch the gastric mucosa Dragstedt has shown that in dogs one of the most satisfactory methods of establishing an experimental peptic ulcer in the pyloric portion of the stomach is to insert sutures in the mucosa, ulcers are much more difficult to create nearer the cardia In case there should be anything in this applicable to man I release the stomach clamp after suturing the peritoneum on the posterior side of the anastomosis, and after opening the viscera, secure the obvious vessels and then carry the needle for the second row of sutures down to, but not through, the mucosa By omitting the duodenal clamp I have been able to make one or two interesting observations One can pass a finger into the duodenum and feel the ulcer crater in some cases, and this helps one to be sure that the cautery (used to destroy the ulcer) is applied accurately to the base of the ulcer Done from the outer side alone this is not always such an easy thing to be sure of A second point has reference to suturing over the ulcer I have done this consistently, as most surgeons do, to prevent a possible perforation later, and also to close the pylorus temporarily and thereby give rest to the ulcer area; and I think I may say that I have carried out this little manœuvre with as much precision as anyone who does not actually pass a ligature round the gut Yet, since omitting the duodenal clamp and exploring the interior of the duodenum after applying these sutures I have, not infrequently, been able to pass my forefinger into the stomach easily and at other times have come up against a diaphragm which would allow a large lead pencil to pass, and this diaphragm has sometimes been due to the pathological stenosis and not to the sutures I have never found a complete block established by the stitches

After-treatment

There is one important point in after-treatment It is generally thought that vomiting is more pronounced immediately after gastro-duodenostomy than after gastro-enterostomy, and in my experience this is true I was much puzzled to account for this, and was inclined to think at first that it was due to the anastomosis becoming involved in adhesions; I felt so sure of this that in one of my earlier cases, where vomiting was very persistent I reopened the abdomen about the fourth day after the first operation, only to find the anastomosis quite patent and entirely unincumbered by adhesions I found the explanation, or what I believe to be the *explanation, quite* by accident when operating on a dog In this animal merely touching the duodenum and the pyloric part of the stomach is sufficient to throw them into the most violent spasm, indeed, they become as hard and firm as a piece of solid rubber, and *remain in this* condition so long as they are being handled The intestine beyond the duodenum does nothing comparable to this Though we do not see anything in man *in anything like this* degree, we do see minor states of spasm, and I have no doubt the handling of the duodenum, especially whilst mobilising it, throws it into an irritable state from which it takes some time to recover. Now I put all my cases on to continuous rectal glucose immediately after operation, and do not allow them anything by mouth for 24 to 48 *hours*, and since doing so I have had no more trouble from vomiting than after gastro-enterostomy.

Results

There have been two deaths, *both patients* were very emaciated before operation and I *think might* have been saved if I had kept them longer on rectal glucose and added intravenous glucose and hypertonic chloride to the pre-operative treatment. Three cases returned with some abdominal discomfort, flatulence and marked constipation, and were, apparently, cured by medical attention to the bowels All the other cases, so far as I have been able to trace them have had no trouble at all, they eat anything and abuse their stomachs with as much *freedom from discomfort* as the average normal person.

There have been no instances of attacks of discomfort, flatulence, and diarrhœa following indiscretions in diet and so on, such as are seen after gastro-enterostomy in a certain number of *cases*—probably *from 10 to 15 per cent.* This sequel *seems to be due* to the stomach emptying rapidly into the jejunum a part which is not intended to receive the stomach contents direct, and without a sufficient mixing of the contents with the important *secretions poured* into the duodenum. This is what the American literature speaks of as the "dumping *stomach.*" In this connexion the recent paper by Mellanby (The Lancet, July 31st, 1926) showing the close relationship between acidulated *food in the duodenum* and *the* effective secretory activity of the liver and pancreas, is interesting.

I have had no anastomotic ulcers when doing *gastro-duodenostomy* for chronic duodenal *ulcer* There has, however, been one certain, and *another* doubtful, case after doing the operation for a gastro-jejunal ulcer following a previous gastro-enterostomy This is rather a different thing from an anastomotic ulcer after a primary gastro-duodenostomy nevertheless it makes one hesitate in asserting that a new ulcer is never to be expected after this operation. If such an event should arise, however, one would still be able to do a *posterior* gastro-enterostomy, instead of the more serious and usual operation of partial

THE IMPORTANCE OF MOTILITY OF BACTERIA

IN CLASSIFICATION AND DIAGNOSIS WITH SPECIAL REFERENCE TO *B. pseudotuberculosis rodentium.*

By J. A. ARKWRIGHT, M.D. Camb., F.R.C.P. Lond., F.R.S.

(From the Bacteriological Department, Lister Institute)

The character of motility was *formerly* highly rated as a ready and reliable guide in classification and diagnosis of bacterial cultures and no doubt the ability of a species or group of bacteria to form flagella must be recognised as very important from the point of view of evolution and classification.

As the result of laboratory experience in connexion with infective intestinal diseases, the use of motility as a diagnostic character has been largely abandoned in practice or given a less important position, since the *motility even of normally highly* motile organisms *such as B. typhosus may* be difficult to demonstrate, except in cultures kept under special conditions or of a certain age, and recently isolated strains sometimes are non-motile, or very slightly motile, when first examined. *Of recent years it has been recognised* that completely non-motile varieties of certain species, usually motile, such as *B. typhosus* or *paratyphosus*, may be met with. In 1903 Smith and Reagh described *motile and non-motile* forms of the hog-cholera bacillus and their distinctive agglutination peculiarities. Weil and Felix (1917) have emphasised the same features in the *proteus* group in dealing with their *B. proteus* X19 and its *H* amd O forms The same authors and their colleagues have extended these observations to the similar variants in the typhoid-paratyphoid *group, and Balteanu (1926) has* recently shown that *V. choleræ* can also be obtained in an O or non-motile form, which has characters analogous to those found in *B proteus*, &c.

The absence of motility is often a temporary *feature* of a culture, and may be only the fugitive result of growth on special conditions—e g, *on* carbolic agar (0·1 per cent.) or in media of low nutritive value. A non-motile variant may, on the *other hand*, be apparently permanent and irreversible. The presence or absence of motility under these different circumstances has been consistently correlated with definite changes in the agglutination phenomena.

Motile *bacilli* of the intestinal group agglutinate in loose, flocculent, cumulus-like clumps, whilst non-*motile* forms agglutinate *more* slowly, often to a much lower titre, and in small clumps which are deposited in larger or smaller coherent granules It has been shown, moreover, that after heating an emulsion of the motile form to 100° C. for one or two hours or *even* for a shorter *period*, agglutination only occurs in granules, and the heated *emulsion* may be quite unable to excite in rabbits the production *of* agglutinins for the flocculus-forming or heat-labile antigen.

Dysentery bacilli, being non-motile, do not agglutinate in loose floccules, but mainly in coarse granules.

B. pseudotuberculosis rodentium has in the past *generally been* considered a non-motile *organism*, and it is safe to *say that* the great majority of bacteriologists of the present day so regard it A. Pfeiffer (1889), who originally described this bacillus, Zlatogoroff (1904), MacConkey (1908), Petrie and Macalister (1911), and Kakehi (1916), all categorically stated that it was non-motile There have, however, been some dissentient voices. Galli-Valerio (1902), who *pointed out* that this bacillus was with difficulty to be distinguished *from B pestis*, affirmed that the latter was non-motile in spite of *the contrary* opinion of Kitasato; he does not however, actually mention this characteristic in speaking of *B pseudotuberculosis* The only writers *who claim* to have observed motility are Kossel and Overbeck (1901) *and* Byloff (1906). The former, after describing their failure to *demon-*

strate motility of *B. pestis* grown at various temperatures, state that all of three strains of *B pseudotuberculosis rodentium* which they examined were motile when grown at room temperature, but not at 37° C They made these observations at low temperatures because Mironesco (1899) had reported on the motility at similar temperatures of a bacillus somewhat resembling *B typhosus* which was non-motile at 37° C Byloff said that motility was only slight and not readily observed. Both Klein (1899) and Byloff (1906) succeeded in staining flagella, and stated that they were terminal, short, and single Plasaj (1921), while admitting that he did not observe motility, stated that a single flagellum could be stained, but could only be demonstrated clearly in few individual bacilli He describes its position as not terminal but "extrapolar," and doubts whether bacilli with terminal flagella could belong to the same species

Resemblances between B pseudotuberculosis rodentium and B. pestis.

The characters of *B pseudotuberculosis rodentium* have been very thoroughly examined on account of its close resemblance to the plague bacillus MacConkey (1908) and Petrie and Macalister (1911) showed that the fermentation reactions of the two were almost identical.

It was pointed out by Zlatogoroff (1904) that *cross-agglutination* could be obtained between the two species This was confirmed by subsequent observers, and MacConkey (1908) and Rowland (1912) confirmed the existence of cross-immunity reactions, and showed that guinea-pigs could be protected against *B. pestis* by a vaccine made with the *B. pseudotuberculosis*

The resemblance between the two organisms was so close that Petrie and Macalister (1911) found great difficulty in deciding to which species certain strains isolated from rats belonged Almost the only reliable distinguishing character appeared to be the ability of *B. pestis* to produce acute septicæmia and death in rats.

The present writer recently had occasion to examine broth cultures of *B pseudotuberculosis rodentium* microscopically for the presence of clumps The cultures grown at 37° C were usually quite non-motile, but in the case of one strain a very few motile bacilli were seen He was at that time unaware of Kossel and Overbeck's observations It was at first supposed that these were contaminants The strains were plated on agar, and appeared to be pure with characteristic colonies Single colonies were picked off and grown in broth at 37° C. and at room temperature (18°–22° C), since it had been noticed that agar cultures at room temperature gave a more copious growth, which formed a more uniform and stable emulsion than those grown at 37° C It was now found that broth cultures at 20° C. were motile Eight strains of *B pseudotuberculosis rodentium* were examined, of which two had recently been isolated from guinea-pigs by Mrs Barratt, and six were obtained from the National Collection of Type Cultures Of these, only one was slightly motile at 37° C , but all were motile when grown at 20° C Some were very highly motile, others much less so. The difference in degree of motility consisted in the number of obviously motile organisms which swam across the field of the microscope One strain which was at first only very slightly motile, after a few subcultures, was observed to be very much more motile These cultures, after having been at room temperature for two days, were placed in the cold room, and were still motile after a month at −5° to +5° C. The identity of these strains with the classical *B. pseudotuberculosis rodentium* was shown (1) by obtaining the characteristic reactions in carbohydrates, &c , (2) by inoculating guinea-pigs, some intraperitoneally and others intracutaneously—typical lesions resulted in the glands and organs, and from these animals the same organism was again isolated from the blood and organs in pure or nearly pure culture, (3) by cross-agglutination with *B pestis* Agglutinating sera were prepared from two of the strains, which both agglutinated all the eight strains of *B pseudotuberculosis* and also 10 strains of *B pestis* The titre of the sera was 1 in 1280–2560 for the homologous species and 1 in 160–640 for the strains of *B pestis* All the emulsions for these tests were grown at 20°–26° C

The agglutination reactions showed that *B pseudotuberculosis rodentium* conformed to the rule for motile bacteria, in that emulsions heated at 56° C for 30 minutes agglutinated in loose flocculi to the limit of the titre, but after being heated at 100° C for one hour, they did not clump in this manner Emulsions heated at 100° C in the case of two strains were agglutinated in granular form at a lower titre, 1/160 to 1/1280 respectively The agglutination of *B pestis* was not flocculent, but occurred chiefly in very small clumps, many of which were only visible under the microscope, but formed a very definite agglutination deposit with complete clearing of the supernatant The emulsions of *B pestis* were no longer agglutinable after being heated at 100° C

The motility of *B. pestis* has been almost universally denied, but Kitasato stated in his original description that it was slightly motile, and Gordon (1897) claimed success in staining flagella and described the appearance of an occasional motile bacillus from agar cultures It is, therefore, interesting to find that the agglutination of *B pestis* by the serum made with *B pseudotuberculosis* is due to heat-labile substance such as is usually associated with flagella Cultures grown at different temperatures of all the strains of *B pestis* used in the present investigation have been examined very carefully on several occasions, but no suggestion of motility was ever detected

Motility in Relation to Parasitism

It is also of interest to note that the non-motile form of *B pseudotuberculosis rodentium* appears to be that which is adapted to parasitism, since the temperature at which alone motility can be observed —viz , 18°–26° C —is not one which the bacillus would experience in the mammalian animal body. This adaptation of the non-motile form to parasitism is perhaps analogous to the occasional isolation of non-motile *B typhosus* from carriers and cases of typhoid fever, and the high virulence of a non-motile form of *B paratyphosus* A isolated by the present writer A somewhat parallel case to the cross-agglutination of *B pestis* and *B pseudotuberculosis* exists in the relationship between *B whitmori* and *B mallei* (Stanton and Fletcher, 1925) These two bacilli produce very similar diseases, melioidosis and glanders, but may have different appearances in culture, and while the former is motile, the latter is non-motile

Summary

(1) *B pseudotuberculosis rodentium* is motile when cultivated at 18°–26° C , but not as a rule when grown at 37° C This is in accordance with the statement of Kossel and Overbeck, made in 1901

(2) This observation is also in harmony with the statements of Klein (1899), Byloff (1906), and Plasaj (1921) that they had demonstrated flagella in stained films of this bacillus

(3) This organism also shows evidence of possessing heat-labile and heat-stable antigens like the bacteria of the typhoid-coli group

(4) It would appear that the motility of *B pseudotuberculosis* when grown at 20° C is sufficient to distinguish it from *B pestis*

CONCENTRATED CARBON-ARC LIGHT.

A SIMPLE METHOD TO IMPROVE THE EFFICIENCY OF THE FINSEN TREATMENT

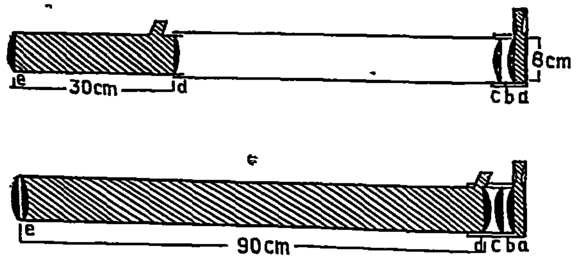
By SVEND LOMHOLT, M.D , O B E

(*From the Finsen Institute, Copenhagen Director A Reyn*)

Finsen's treatment of lupus vulgaris with concentrated rays of a carbon arc remains the unrivalled *traitement de choix* of this troublesome disorder, though it is rather expensive The strong heat, resulting from the powerful heat rays of the carbon arc, prevents the raising of the intensity of the short wave irradiation above the amount produced by a carbon arc of 50 amps , 55 volts and filtered through 31 cm of water The construction of this is shown in the drawing (Fig 1)

Finsen made many attempts to improve this construction, and especially to reduce the heat, but without any perfect success At last he restricted himself to a water filter of about 30 cm length (Fig 1) which he thought would remove all the infra-red radiation of the light Yet it is clearly seen from the Aschkinass classical investigations on the absorption of water [1] (Fig 2), to which my attention was first drawn by Dr W Kuhn and Dr D Dennison, that a fairly large proportion of the innermost infra-red rays pass through a water filter of 31 cm , as used in the original Finsen lamp and still more through the 16 cm of the Finsen-Reyn lamp, the two constructions most commonly used at present for local carbon-arc light therapy For the therapeutical use of the carbon-arc light this fact is most important

Fig 1.

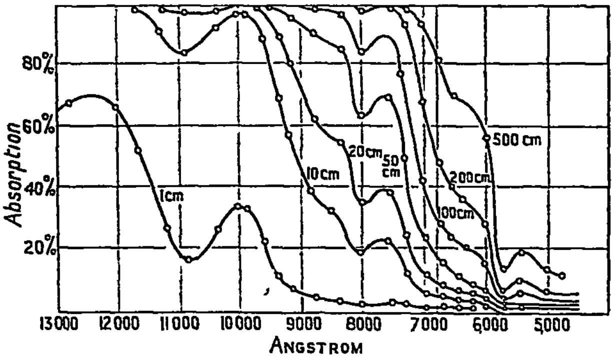


Finsen's original model author's modification a, b, c, d, e, Quartz lenses The hatched area indicates distilled water

In the first place the maximum of energy of the arc light lies at about this place in the spectrum (see the diagram (Fig 3) made by Prof E S Johansen showing the distribution of energy of the carbon-arc light) In the second place the infra-red rays are especially inconvenient in the Finsen treatment, as compared with the luminous rays Sonne [2] showed that the skin of a man's forearm will usually stand an average irradiation of 3 11 g calories per square cm per minute of luminous rays without any unbearable pain, but only 1 77 g calories of the inner infra-red rays, because the luminous rays penetrate much deeper into the skin (several centimetres) than the invisible. Thereby their energy is distributed throughout a much thicker layer of the tissue

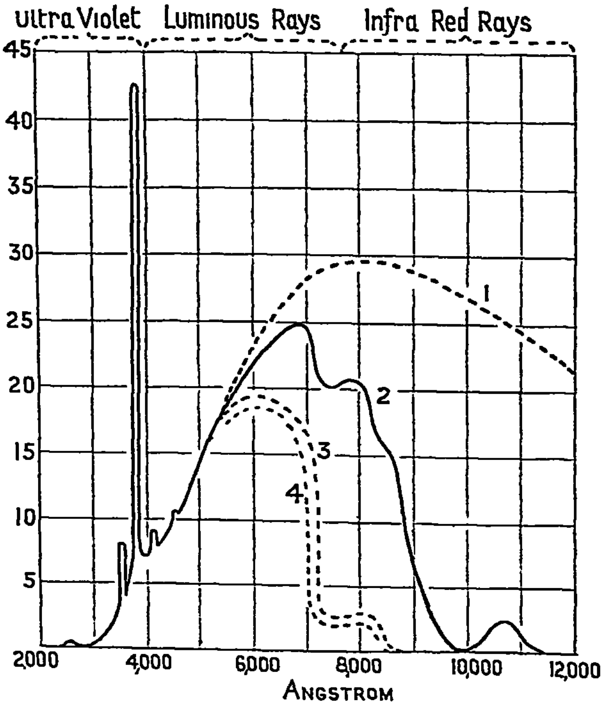
From the curves of Aschkinass and Johansen it seemed evident that an increase of the water filter up to 100 cm of length must be very favourable to make the light column less hot and less injurious to the skin This increase will not affect the efficient " chemical " part of the spectrum. The thermal energy of a light column (from the arc lamp described above), which had passed through the original apparatus of concentration, was now accurately measured and compared with the energy of the same column after it had passed an apparatus with a filter of 90 cm water For these measurements a special instrument was constructed by Mr J. C Jacobsen; a Dewar's vessel was blackened inside and filled with

Fig 2



Absorption of light in water (after Aschkinass)

Fig 3



Energy of the light from a carbon arc (after Johansen) 1 Total energy 2, 3, 4, Energy passing a water layer of 16 cm (Johansen), of 100 cm (calculated after Aschkinass), and of 120 cm respectively

water The opening was closed with a plate of quartz except for a small slide in the upper side to permit the introduction of a thermometer We found this instrument ideal for the purpose The measurements gave the following figures

	(1)	(2)	(3)	
Original construction	125	124	114	gr calories per min
New "	70	76	70	" " " "

Thus, the increase of the water-layer from 31 to 91 cm diminishes the heat of the light column by more than 33 per cent, corresponding well to the figures given by Aschkinass and Johansen (Figs 2 and 3)

The therapeutic experiments gave a result which was in perfect accordance with this The treatment with the new apparatus proved to be almost painless, even to very sensitive patients Fortunately, the therapeutic effect—i e, the reactions on the skin (redness infiltration, and bulla formation)—remained completely unaffected To make certain of an unreduced therapeutical effect, a series of six double biopsies were made on six patients, who received each one spot treated with the original and one spot with the new construction Three of the patients were treated on lupus plaques three on sound skin The examination showed that the histological changes were perfectly equal as far as each of the six different pairs were concerned The most important result of the described reduction of the heat rays is that it permits of a corresponding increase of the irradiation, and even somewhat stronger up to about 50–60 per cent, without being painful to the patients The reaction of the skin after one hour of this radiation seemed to be not much inferior to that of two hours of the original construction These facts were also confirmed by histological examinations The perfect tolerance of the patients under this very strong treatment is probably due to the fact that the part of the light which is removed by the thick water column contains just the infra-red irradiation which is especially painful to the skin because of its superficial effect and absorption

Conclusions

1. Water is an ideal filter to be used in carbon-arc therapy It lets the efficient ultra-violet rays pass untouched even through thick layers

2 A water layer of 91 cm absorbs almost all the infra-red and a good deal of the outer red rays in the light—i e, of rays of 7300 Angstrom still about 50 per cent are absorbed Calometric measurements showed that a light column, which has passed an apparatus of concentration with a water filter of this thickness, contains 30–45 per cent less heat than a corresponding column that has passed one of the original apparatus with filters of 31 and 16 cm (Finsen and Finsen-Reyn lamps) The filter does not diminish the therapeutic effect of the light

3 According to Sonne's investigations the absorbed infra-red and red rays represent the part of the irradiation of the carbon arc most inconvenient for light therapy since they are absorbed in the uppermost layer of the skin in which very sensitive part of the body they produce a strong heating that gives rise to severe pain Consequently, the elimination of them will permit an increase of the intensity of the irradiation which is considerably stronger than the said 30–45 per cent that is their part of the thermical energy of a carbon-arc light column, which remains after it has passed a water layer of 16–31 cm

4 Clinical and histological observation showed that it is possible to increase the biological effect of the concentrated carbon-arc light by using water filters thicker than the ordinary ones and this considerably more than indicated by the 30–45 per cent mentioned

---

COST OF IRISH MENTAL PATIENTS —The Department of Local Government of the Irish Free State has issued a comparative statement showing the annual cost of maintaining mental patients in the State institutions The figures range between £55 16s 11d at Kilkenny and £40 12s 8d at Castlebar, the average is £19 1s 4d In most cases there has been a reduction as compared with 1925

THE TREATMENT OF TUBERCULOSIS BY MR SPAHLINGER'S METHODS

BY THOMAS NELSON, B M, B CH OXF
M R C P LOND,
ASSISTANT PHYSICIAN TO ST GEORGE'S HOSPITAL AND
TO THE BROMPTON HOSPITAL

FROM time to time certain persons in this and other countries but particularly in this country, strongly advocate the expenditure of large sums of public or private money to assist Mr Henri Spahlinger of Geneva to apply his secret remedy for tuberculosis to "sufferers" in general Hitherto there have been published for the medical profession and others interested in this matter few if any, accurate records of cases treated by this method The only data on which to form an opinion so far available have been of the nature of eulogies of this remedy citing remarkable cases of "cure" And these are to be found mostly in the non-medical press

Selected Cases Treated in 1913–14

Yet we have in this country a most careful and full record of ten cases treated under the immediate supervision of Mr Spahlinger himself between November, 1913, and August, 1914 This work took place in a London teaching hospital under conditions ideal for research It was under the supervision and with the cooperation of a very learned and wise physician whose opinion on such a matter would carry almost universal conviction During this period the late Dr Arthur Latham gave these selected cases as a test for Mr Spahlinger The treatment was carried out personally by Dr J W Linnell, with Mr. Spahlinger actually at his elbow Dr Linnell was at that time working with Dr Latham as Gibbons Research Student The usual precautions were taken to explain the experimental nature of the treatment to the patients concerned (and to the parents of the younger ones) The choice of having the treatment or not was left to the patient's own inclination

The records of these cases are here set forth as obtained from the medical notes of St George's Hospital There were about an equal number of cases treated at the same time, under similar conditions, in nursing homes Owing to the untimely and deeply regretted death of Dr Latham all records of these have been lost in the destruction of his private notes Of these ten, I have succeeded in tracing the after-history of eight Of the two untraced, I have hardly sufficient information to identify them with certainty, even supposing I could find their names in the Registrar-General's records at Somerset House

These cases were selected by Dr Latham with the utmost care and skill They were all (with one possible exception) of rather advanced chronic type not immediately and absolutely hopeless So that although few in number, they are the sort of cases in which an arrest of the disease with a return to reasonable health and life on the part of several of them would have indicated the presence of a curative agent in Mr Spahlinger's preparation of such a nature as we have at present no knowledge

Many of them had had previous courses of "aurocyanide," with negative results Dr Latham was testing this forerunner of sanocrysin at that time Two of the cases were especially chosen to test the effect on lupus and spinal caries

The Ten Cases Related

In tracing the after-histories, I am deeply indebted to Miss Hamilton, lady almoner of St George's Hospital, for her diligent search The extent of infiltration in the lungs was judged in all cases both by physical and radiographic methods Here are the cases in detail —

CASE 1 —I H, female, aged 37, admitted Nov 11th, 1913 Cough for many years A recent hæmoptysis of

2 pints No family history of phthisis An old arthritis of left ankle and knee (? due to the intracellular diplococcus) An infiltration of all left lung and right apex T B + + in sputum Only slightly febrile From November to January a course of aurocyanide injections without much improvement, but some gain in weight February to May, 26 injections of Mr Spahlinger's preparation, each giving brisk febrile reactions Signs in lungs drier T B in sputum, three found by antiformin method Weight maintained Discharged June 9th, 1914

Untraced Not known at any original addresses, or address of brother The M O H 's of Wandsworth and Westminster, in which districts she is known to have lived, have no trace except her original notification

CASE 2—A H, female, aged 29, admitted Nov 20th, 1913 Tuberculous hip-disease as a child, now healed Always had a cough Lupus on face for years Had been treated for some time with tuberculin injections and Finsen light Both father and mother died of tuberculosis Two brothers and one sister died of chest trouble Hip appears healed Moderate patch of lupus on face An occasional asthmatic attack in hospital—slight Signs in lungs indefinite contracted and rather opaque apices Sputum examined 14 times T B + once and two bacilli found on one other occasion Afebrile November to December, 1913, had 18 injections of aurocyanide Lost 5 lb. in weight February to August, 1914, had 29 injections of Mr Spahlinger's remedy Brisk short reactions Regained 5 lb. of weight Discharged August 18th, 1914

The lady almoner of Guy's Hospital reports she saw this lady alive in May, 1926 She had married seven years previously, and was seeking advice for a suspected pregnancy Her face was very much disfigured with lupus, for which she had had no treatment for years

CASE 3—M H, female, aged 37, nurse, admitted Dec 18th, 1913 A cough for four years Tuberculosis diagnosed 18 months ago Has had courses of tuberculin and sanatorium treatment Has lost 2½ st in all Voice rather husky A general infiltration of both lungs with one fair-sized and several small cavities at the left apex. Early tuberculosis of the larynx Sputum T.B + + Moderately febrile From January to March, 12 injections of aurocyanide Lost 4 lb Physical signs stationary April to July, 17 injections of Mr Spahlinger's preparation Physical signs unaltered Sputum less in amount, and T B —, rather fewer Lost five more pounds in weight. Discharged July 23rd, 1914

The tuberculosis officer of Berkshire reports that she died in 1915

CASE 4—M C, male, aged 27, traveller, admitted Nov 15th, 1912 Cough for one year, wasting, &c Two maternal uncles died of phthisis Signs of infiltration in right lower lobe T B + in sputum Was discharged to sanatorium after one month in hospital No record of time in sanatorium But cough and pain in chest returned shortly after as bad as ever, and was readmitted to St George's on Jan 26th, 1914

Well nourished T B + + in sputum Consolidation and cavitation in upper two-thirds of right lung. Some slight general infiltration of all left lung A low intermittent pyrexia lasting a few days at a time Often goes a week at a time with normal temperature February to May, 24 injections of Mr Spahlinger's preparation Very marked reactions with rigors and vomiting Lungs drier T.B + + in sputum Amount of sputum diminished Discharged June 4th, 1914

On June 30th 1914, was readmitted for a second course, having had two injections as an out-patient Three further injections given as in-patient Weight stationary, sputum scanty, but T.B still + + Discharged July 20th 1914

A letter from the patient's mother dated June 5th, 1926 says " after leaving St George's (he) spent the winter at Brompton Hospital, and from there went on to Frimley, where he gained much benefit so that in the autumn of 1915 he entered into business . He got on very well He got married in March 1917 (And later on that year) he quite broke down and went to Margate for a change He passed away in September 1917 "

His death is confirmed by the M O H for the Borough of Stoke Newington

CASE 5—T T, male, aged 50 clerk, admitted March 7th, 1914 He had been treated for three months outside hospital immediately before admission by Mr Spahlinger Cough and "asthma" for five years Lost a good deal of weight in the last two years Voice hoarse for seven weeks One brother died of phthisis Considerable infiltration of both lungs T B + in sputum Wassermann negative Sputum 2 oz per day Very marked tuberculosis of the larynx Temperature irregular but never above 99° F Was discharged March 16th, 1914, for further treatment by Mr Spahlinger outside the hospital

The M O H for the Borough of Lewisham reports that he died in a nursing home in London in 1914

(*Note*—This case was one of the private ones who came into hospital by chance He had at least 21 injections of Mr Spahlinger's preparation, and probably a good many more)

CASE 6—B M, female, aged 22, typist, admitted March 12th, 1914 She was an in-patient of the hospital in November, 1913, for 11 weeks Signs then showed general consolidation of the right lung with cavitation at apex, and infiltration of the upper half of the left lobe T B + in sputum During this admission she had 11 injections of aurocyanide with no improvement and slow loss of weight

On admission this time had lost another ¾ lb since discharge Her temperature was fairly level Pulse 88–100. Signs as before March to May 17 injections of Mr Spahlinger's preparations Some brisk reactions to intravenous injections Amount of sputum less at first, later increased Physical signs remained the same and T.B — in sputum, as before Lost 2 lb in weight Temperature at end of course tending to be more constantly febrile Discharged May 3rd, 1914

On June 5th, 1914, was readmitted Lost 1 lb since discharge No appreciable change in lungs Sputum less in amount, but T B. now + +. Had six further injections, with reactions as before Had lost a further 3½ lb on discharge Otherwise the same Discharged July 2nd, 1914

She lived at home for some months From March, 1915, onwards she attended the tuberculosis department at St George's at intervals She was admitted to the Brompton Hospital in May 1915 Thence she was sent to the Royal National Hospital, Ventnor A progress report on discharge from this institution on Nov 9th, 1915, shows her condition to have altered little T B still + in sputum and fairly afebrile Through 1916 she appears to have lived at home, doing little and changing little A report in January, 1917, says she was "working" with a temperature of 99° F at 2 P M and pulse of 102 In April the same year a further report says extensive disease both lungs, febrile, œdema of legs, and hæmoptyses. She died April 10th, 1917.

CASE 7—J A., male, aged 22, admitted April 7th, 1914. Had just returned from Malaya, having noticed lassitude, loss of weight, cough and sputum for six months Pale and thin Infiltration upper two-thirds of both lungs, with small cavities at both apices The infiltration is scattered and not very heavy T.B + in sputum Temperature mildly febrile, only occasionally up to 100° at night. April to July, 17 injections of Mr. Spahlinger's preparations. Smart reactions, especially with "serum" Sputum decreased, though T B still + Weight as before Signs the same Discharged July 27th, 1914

A report from the M O H of the counties of Moray and Nairn, dated June 17th, 1926, says: " . . about the outbreak of war in 1914 he was exempted from service, and was engaged for a considerable period as salesman . in Elgin I saw him frequently, when the disease seemed to be fairly quiescent He left this district for the South . . . I lost sight of him till 1921, when he returned home to his parents about October in that year and died about a fortnight later on Oct. 16th, 1921 "

CASE 8—G L, female, aged 31, admitted April 11th, 1914 Four years ago first had pain in her back, which shot down right thigh Eighteen months after that spinal deformity was first noticed but patient continued to work for six months after that Was then under medical care on back for ten months Then up and about for six months From then onwards—i e, last six months—has been on back under further treatment in a sanatorium Had a course of Mr Spahlinger's preparations outside the hospital in January No cough or sputum or other lung symptoms. Angular deformity of several vertebræ in the lower dorsal spine Much rigidity of back, and pain on jarring Lungs have a poor note at left base, otherwise not abnormal. Slight fever at times April to July Treated with 21 injections of Mr Spahlinger's "serum" Very marked reactions Temperature steady between reactions Was walking on discharge with a poroplastic jacket Discharged July 31st, 1914

This patient has not been traced Visits to the home of the parents and relations in West Sussex have revealed no trace of the family, nor any neighbour who knows anything about them

CASE 9—F B, male aged 18, admitted May 4th, 1914. Fourteen months ago developed pleurisy at the left base. Cough, night sweats, &c, since Pulmonary tuberculosis diagnosed six months ago, has improved since Well nourished T.B + in sputum Infiltration of all right lung and left lower lobe Temperature up and irregular. Only three injections of Mr Spahlinger's cure given Some reactions Patient was removed from hospital by his parents before course completed No alteration of physical signs on discharge Discharged June 13th, 1914

The tuberculosis officer of Kent reports that he died on March 1st, 1916

CASE 10 —M O, female, aged 22, admitted May 11th, 1914 Onset of disease 18 months ago with cough, sputum, night sweats, wasting, &c One year ago was sent to sanatorium for a period of six months Signs of infiltration in the right lung and left upper lobe T B + + in sputum Irregular swinging temperature, average 101 5° F at night May to June, six injections of Spahlinger's preparations Lost weight all the time Signs spread to rest of left lung T B + + in sputum Discharged July 8th, 1914

The tuberculosis officer for the Borough of Fulham reports that she died in Fulham Infirmary in the same year—1914

Summary of Results

The following table summarises these results briefly —

Case	Sex	Age	Site of disease	No of inject	Immediate result	Further treatment	Final result
1	♀	37	Lungs	26	Sl imp	N tr	N tr
2	♀	29	Lupus	29	No change	? Finsen light none for yrs	Alive, married 1926
3	♀	37	Lungs	17	Sl worse	No record.	Died 1915
4	♂	27	,,	29	Very sl better	Brompton Frimley	,, 1917
5	♂	50	,,	24*	No change	—	,, 1914
6	♀	22	,,	23	Sl worse	Brompton Ventnor	,, 1917
7	♂	22	,,	17	? Sl imp	None	Worked, died 1921
8	♀	31	Spine	21	Imp	N tr	N tr
9	♂	18	Lungs	3	No change	No record.	Died 1916
10	♀	22	,,	6	Rapidly worse	Fulham Infirm	,, 1914

* Two courses (24 at least)
Sl. imp =Slightly improved N tr =Not traced

Conclusion

They may be shortly reviewed thus The case of lupus is still alive. Lung lesions are notoriously benign, as a rule, in individuals with lupus The spinal case is untraced, but may possibly be alive—such cases do live for years One of the lung cases is untraced Of the remaining seven all are dead It is difficult to say that any of them showed any improvement after their treatment, certainly none showed marked improvement Such slight indications as there are of improvement are not more than one would expect from tuberculous patients after they had been in bed for periods of time such as these were The two who lived to 1917 both had much further orthodox treatment at the Brompton Hospital, Frimley, and Ventnor The one who died in 1921 is one of those cases to be found in any tuberculous series who lives longer than one would expect Also he was the patient in this series with the least disease and the shortest history

---

SWINDON HOSPITAL SERVICE —For a long time past there have been serious difficulties connected with hospital accommodation at Swindon, and the town council recently sought a way out by proposing to purchase an expensive site for the creation of a municipal hospital The Ministry of Health has, however, refused to sanction the purchase on the ground that the case for a municipal hospital has not been made out

BIRMINGHAM HOSPITAL SATURDAY FUND —This year's collections amounted to the record sum of £64,500, and after providing for the Fund's own convalescent homes and special expenditure, £26,000 is being distributed to hospitals and institutions In addition £5250 has been spent on hospital tickets, £3500 has been given as a special grant to the guardians, and £5250 contributed to the Droitwich Hospital for the Treatment of Rheumatism

Clinical and Laboratory Notes.

A CASE ILLUSTRATING THE EFFECTS OF PROLONGED APPLICATION OF COLD TO THE EYE

BY K E MADAN, M D BRUX, D O M S ENG,
OPHTHALMIC SURGEON TO THE PARSEE GENERAL HOSPITAL, BOMBAY

THE following case seems to be worthy of record —

A myopic woman, aged 52, who was suffering from traumatic subconjunctival ecchymosis in the left eye, was advised by her doctor to keep an ice-bag constantly over her eye, in order that absorption of the blood might be hastened Unfortunately she kept up the treatment for nearly a fortnight, the subconjunctival hæmorrhage mostly cleared up within the first few days, but after about a week the patient developed severe neuralgic pain on the left side, and, after a fortnight, acute congestive glaucoma in the left eye, with ptosis

There was marked increase of intraocular tension, severe pain and tenderness haziness of cornea (vision being reduced to nearly 3/60), and contracted fields of vision of the glaucomatose type She also suffered from violent neuralgic pain in the left forehead and temple, the skin over the course of the left supraorbital nerve was very tender, and the patient retracted her head at once whenever the supraorbital region was touched The ice bag lying on her left forehead was responsible for this complaint also

When I saw the patient in this condition eserine drops were at once instilled, and she was put on bromides, salicylate, hyoscyamus, and gelsemium mixture, with fomentations to the eye, the left temple was blistered. To relieve her supraorbital neuralgia, soothing applications were given, but as the glaucomatous pain in the eye persisted with high tension, I trephined her, with the result that she had immediate relief from pain and the haziness of the cornea cleared up, giving her a greatly improved vision She recovered, but the ptosis persisted for nearly a week more

The trauma which caused the ecchymosis cannot be regarded as responsible for the glaucoma, which developed a fortnight afterwards The points of interest in the case are (1) that acute congestive glaucoma occurred in an eye with as much as eight diopters of myopia, which is unusual, (2) that the attack of congestive glaucoma was brought on by the prolonged application of cold on the eye, and (3) that trephining for acute glaucoma showed itself just as satisfactory an operation as iridectomy

It may be mentioned that subconjunctival ecchymosis coming on several days after an injury indicates fracture of the base (anterior fossa) of the skull If, however, ecchymosis comes on immediately after the injury and is not associated with any other intraocular lesion, it is not in any way serious, and always takes its time to clear up Prolonged application of ice on the eye is unnecessary and injurious

BLACKWATER FEVER IN SCOTLAND

BY JAMES S ANDERSON, M D ABERD, D P H,
SENIOR RESIDENT MEDICAL OFFICER, CITY HOSPITAL, ABERDEEN

IN view of the rarity of blackwater fever in this country, the following case appears to be worthy of record

The patient, D M, aged 28, was a native of the Outer Hebrides and had previously enjoyed average good health In 1916 he served in the army in Gallipoli and contracted malaria No record could be obtained of the type of infection, but the disease does not appear to have been severe After a brief sojourn in Scotland he obtained an appointment in Nigeria in 1918, his employment entailing much travelling about the country He left Nigeria for this country on Nov 4th, 1924, apparently in good health From 1916 to 1924 he had kept a record of his malarial attacks, and he reckoned the number as 25, none being of special severity He was certain that he had never shown any manifestations of blackwater fever during that period

Having spent the winter months in Lewis, he started out on his return to the West Coast of Africa early in March

1925 Arriving in Aberdeen during a snowstorm, he lodged in a hotel where the present illness developed suddenly on March 12th The onset was heralded by a rigor, followed by irregular fever with marked bilious symptoms On the first day the patient took 15 gr of quinine sulphate by mouth, but this does not appear to have been retained On the following day he was alarmed to find that he was passing very dark urine The symptoms becoming worse, he was admitted to hospital on March 14th

Condition on admission—Temperature 100° F, pulse-rate 88 There was some epigastric distress and vomiting of a bilious type was severe and prompt after any attempt to swallow fluids Splenomegaly was present, the organ being just palpable, while the liver appeared to be normal in size The skin and sclerotics showed a marked saffron yellow tint. On the day of admission and on the following day he passed a few ounces of urine of a mahogany colour He was constipated. All the symptoms increased in intensity until March 16th after which they gradually subsided The vomiting was particularly severe, necessitating the use of a small amount of opium. The only fluid tolerated for any time by mouth was iced champagne, so that frequent rectal and intravenous administration of normal saline was a necessity. No urine was voided after March 15th, and constipation defied all attempts to procure a movement of the bowel A feeling of intense weakness developed, and as a result of the suppression of urine slight convulsions appeared on March 22nd, rapidly terminating in coma and death on the same day

Blood films failed to reveal the presence of malarial parasites, and the red corpuscles showed no abnormality The white cell count on the day after admission was as follows. polymorphonuclear cells 74 per cent, large mononuclear cells 13 per cent, small lymphocytes 11 per cent, eosinophil cells 1 per cent., and transitional cells 1 per cent. The fæces showed no pathological organisms and no unusual protozoa. The urine contained a large amount of albumin and a large deposit of brownish granular material Blood corpuscles were entirely absent and spectroscopic examination gave the characteristic bands of oxyhæmoglobin.

A noteworthy point in connexion with this case is that the disease developed more than four months after the patient had left an area in which it was endemic.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF ELECTRO-THERAPEUTICS AND SURGERY.

SURGICAL ASPECTS OF DIATHERMY

A MEETING of these Sections was held on Dec 17th, when there was a discussion on the surgical aspects of diathermy. Dr G BATTEN (Electro-Therapeutics) took the chair.

Dr. E P CUMBERBATCH opened the discussion, his main purpose being to deal with the technical aspects of surgical diathermy and the methods of performing the operation The temperature of tissues, he said, could be raised by passing through them a current of considerable intensity. By making this current alternate with high frequency the undesirable stimulation of muscles and nerves and the production of electrolytic changes in the tissues were avoided, and by confining the current within a narrow path the tissues in that path were deprived of their vitality. Hence such a process was available for surgery

Diathermic Coagulation.

To produce coagulation of abnormal tissue said Dr Cumberbatch, the current was increased sufficiently to cause a high temperature, an electrode of small area being placed on the tissue to be destroyed, and the circuit completed by a large area electrode placed on another part of the body Eventually, under the influence of the gradually increasing current the tissues began to boil, and later sparks passed from the edge of the disc, over the coagulated (now dried) tissue to the uncoagulated part beyond The current should not be continued after the appearance of the sparks, as the coagulation would only very slowly proceed to a greater depth The difficulty of application by means of the disc electrode was that the operator could not see the extent, in depth, of the tissue coagulation Experiments carried out on excised tissue showed that the depth of the coagulation equalled the diameter of the disc In living tissues the circulation removed some of the heat generated by the current and prevented the coagulation from spreading. but destruction took place beyond the limit of coagulation—a point to be remembered when important structures were in close proximity The depth of the coagulation was much more under control when a single needle was used instead of a disc Coagulation commenced at the needle point, then proceeded up the shaft to the surface, and the depth of coagulation was determined by the depth of insertion of the needle, and the coagulated mass took the form of a narrow cylinder. By putting the needle into a number of sites closely adjacent to each other destruction of a wider area could be brought about With multiple needle electrodes there could not be the same certainty as to the depth of the destruction brought about.

Circumvallation and Operations with the Blade Electrode.

Circumvallation, continued Dr. Cumberbatch, was the operation by which a malignant growth was surrounded by a rampart of coagulated tissue The single needle electrode was put obliquely into the healthy tissue adjoining the growth to a point below the growth and the tissue was coagulated around it. By repeating this in adjacent parts in succession, the needle being each time directed to the same point below the growth the coagulated rampart would be cone-shaped and the growth would be imprisoned within it. Diathermy of the growth would not now be likely to cause metastasis This method was being widely practised in America

In the old method of using the blade electrode it was inserted into the healthy tissue around the growth and was moved forward slowly enough for coagulation to keep in advance of the cutting edge The blade must cut only coagulated tissue which was difficult to ensure. and if other tissue or unsealed vessels were cut bleeding occurred, with its disadvantages and risks By the new method a strong current was produced before the blade was brought into contact with the tissue Contact was then made and the blade drawn into and across the tissue with the same speed as the scalpel was used in a cutting operation. The tissue divided as the blade was drawn across it, and a white line of coagulation marked the track of the electrode. The facility of division of the depth of coagulation of the divided surfaces varied with the different diathermy machines; those giving a maximum current at a relatively high voltage were less suitable than others. With a low voltage tissue was divided easily. but the amount of coagulation was slight.

The best way to deal with accessible malignant tissue, said Dr. Cumberbatch, was to do a preliminary circumvallation and then remove the growth by the blade electrode When there was widespread disease so that circumvallation could not be done, it was best to accomplish as much coagulation as possible by means of the disc electrode and allow the tissue so isolated to separate spontaneously. After diathermy healing was rapid, even if complete destruction had not been brought about, and any recurrence could be dealt with in a similar way.

Fulguration

In the operation of fulguration. he continued. the tissues were destroyed by the heat derived from sparks The surface might be carbonised by the sparks, but the destruction by this method was not very deep. It was suitable for destroying papillomata of skin and mucous membrane and in America hæmorrhoids and enlarged tonsils were treated in this way. Whilst in New York he had seen Dr. W. Bierman operate for hæmorrhoids by this method.

He first injected a dilute solution of novocaine into the sphincter ani, the sphincter was then dilated, an earth connexion was made. and sparks from an Oudin resonator played on to the hæmorrhoids, which became thus reduced to dry masses. The only pain felt was that due to insertion of the syringe needle and the patient could go on with his ordinary work in two or three days. For enlarged tonsils surface anæsthesia was produced and the sparks were applied by special directors to prevent other parts receiving them. This was done again at intervals of two or three weeks until complete removal had been effected.

Electro-Desiccation and Wyeth's Cutting Current

By the method of electro-desiccation devised by W L Clark, of Philadelphia, said Dr Cumberbatch, a current of low amperage was passed through the tissue by a needle electrode, thus dehydrating it. It could be accurately localised and was under the complete control of the operator. Even corneal ulcers and papillomata of the vocal cords could be treated by it; the cosmetic results were very good and the inflammatory reaction slight. The latest advance in the use of high-frequency currents in surgery had been made by a New York surgeon, G A Wyeth. He used the current for cutting and for coagulating the cut surfaces, the coagulation being limited to a depth of 0.1 mm. He employed a current with a sustained oscillation, the alternation being at the rate of about five million per second. Healing by first intention would take place after the tissue had been divided in the way described. Post-operative shock was said not to occur.

Discussion

Mr F J. Steward said that his experience with diathermy was confined to new growths on the surface of the body or in the mouth or pharynx. Its superiority over the cutting operation was evident if certain conditions of technique and choice of cases were satisfied. The final results from the two methods were identical. Diathermy was almost a bloodless operation and its use was quicker and more precise. The hæmorrhage and post-operative shock after the use of the knife frequently paved the way for sepsis, with, perhaps, secondary hæmorrhage or pneumonia. After diathermy recovery was rapid and complications were uncommon, there was also a remarkable freedom from pain after the operation. This freedom from pain was an inducement to choose the method in carrying out palliative treatment in cases too advanced to give hope of cure. To ensure destruction of the growth together with a considerable amount of surrounding tissue the growth must be thoroughly exposed to vision, this exposure could generally be ensured by retractors, gags, and sutures, though sometimes a preliminary operation might be needed. He had not chosen diathermy when the growth involved bone, for when the sequestrum had separated after diathermy recurrence was usual in the bed which had been occupied by the sequestrum.

Mr. Gwynne Williams said that he agreed almost completely with what Mr Steward had said. He spoke on the use of the method for carcinoma of the tongue and floor of the mouth, for which he had not used the knife for six years. He limited the method to cases which he considered operable. His difficulty had been to keep the diathermy knife going at the correct pace and to keep the current reasonably constant. Sometimes the lingual artery had to be tied and it was always the safer plan to tie as reactionary hæmorrhage was then much less likely. It was just as important for the mouth to be kept clean for diathermy as for an operation with the knife. He agreed that the scar left after diathermy was much softer than that which followed use of the knife. The likelihood of recurrence was the same. For operations on the tongue his practice was to remove the glands in the neck very freely at a separate operation.

Mr Douglas Harmer said that surgical diathermy was first done in England at St Bartholomew's Hospital in 1910 by Prof Nagelschmidt, who was introduced by the late Dr. Lewis Jones. It was for removal of a large pedunculated malignant growth of the nasopharynx. The result was good and there was no bleeding. Sixteen years experience with this method had convinced Mr Harmer that it was better than simple excision with the knife. Indeed, he thought malignant ulcers should not be removed by cutting when diathermy was available. Only two of his cases had succumbed from bleeding. When bone was involved it should be freely destroyed, bone involvement was no contra-indication to the treatment. In many instances radium and X rays were needed either before or after diathermy. Probably by using diathermy in preference to simple excision for malignant ulcers in the upper air passages the number of cures obtained had been at least doubled.

Mr H H Rayner gave an account of his experiences with diathermy in cancer of the skin and of the breast. Not only was the method preferable to use of the knife, but, he thought, the risk of local recurrence was less. In advanced epithelioma of the skin diathermy gave better results than the knife, the surgery was minimal and the ultimate condition more satisfactory. Very advanced cancer of the breast could also be treated by diathermy with considerable benefit.

Dr. Thomas Marlin spoke of the path pursued by the diathermy current and described the results of his experiments on egg, turnip, and beef.

Mr Gordon Taylor said that as a result of his experience with over a hundred cases of operable carcinoma of the mouth treated by diathermy—of which 84 were carcinoma of the tongue—he was convinced that the results in carcinoma of the tongue treated by diathermy were better than after the older method by scissors or the knife. The only disadvantage appeared to be the risk these patients seemed to run of getting broncho-pneumonia after diathermy. Of those who survived the short period after the operation, 50 per cent had a good chance of remaining free for six years. (He had first used the method six years ago.) Secondary hæmorrhage after the operation he regarded as a bugbear. In 84 cases of carcinoma of the tongue he had only had two cases of such hæmorrhage, one was easily controlled, in the other the lingual artery had to be secured. And in inoperable malignant growths of the mouth diathermy was most useful. He had also used diathermy for malignant growths of the bladder.

Mr John Everidge said the diathermic cautery possessed enormous advantages for the treatment of papilloma of the bladder, and the results it gave were quite good. Recurrences were frequent, which was not suprising, for only papillomata which could be seen were destroyed, and the tendency of the bladder to form these growths was unaltered. Sepsis in the bladder did not tend to occur after the method. Secondly, hæmorrhage took place with considerable frequency and there was often a fair amount of bleeding at the end of the first week, but he had not yet had a case so treated which caused him any great anxiety. In the treatment of carcinoma of the bladder by the diathermic cautery, however, the story at his hospital was a different one, for most of the cases seemed to have been the worse for it. Indeed, in cases of doubtful diagnosis as between carcinoma and papilloma, the cautery usually made the nature of the lesion clear, for carcinoma was not benefited. Forage for prostatic enlargement had been found very valuable where there was a projection into the prostatic urethra causing urinary obstruction. It was not so good for massive enlargements. The absence of scar tissue after operation was of peculiar importance in the neck of the bladder and this constituted another recommendation for diathermy.

Mr Philip Turner spoke of his use of fulguration for malignant growths with Dr Iredale in 1909 after he had visited the Surgical Congress in Paris in 1908. Later they had found diathermy superior to fulguration. Rodent ulcer was the type of lesion which yielded the best results. In addition to the diseases mentioned in the discussion diathermy had been valuable for cases of breaking down tuberculous glands in the neck with sinuses, for it brought about firm healing and he was able to support the statements as to the absence of pain and shock and the formation of supple scars after diathermy In his 18 years' experience with it he had had only three burns, and four cases of secondary hæmorrhage He always took care that no ether was in the theatre where diathermy was performed For malignant growths in the mouth and pharyngeal region the method was particularly valuable, as it enabled the mutilating operations—which were so frequently disappointing—to be dispensed with He had employed colloidal copper for the purpose of guiding the diathermy current accurately along the lymphatic tract, and had found it distinctly useful when the neck glands were involved

Mr C G Teall referred to the use of diathermy for treating growths in the œsophagus, a region where it had long been considered dangerous to use it In association with Mr Musgrave Woodman he had used a specially designed electrode constructed of metal only where it was intended to act on the growth, the remainder being of vulcanite , it answered very well for palliative treatment More recently they had used a modification of the Jackson bougie

Mr C P Lankester spoke of his treatment of hæmorrhoids by diathermy and the almost entire absence of pain.

Reply

Dr Cumberbatch, in reply, said that after carrying out circumvallation, pieces of tissue could be excised for microscopical examination without setting up metastasis such as many considered likely when that was done in the ordinary way In Baltimore both Howard Kelly and Joseph Bloodgood had now discarded the knife for accessible malignant growths Experiments in diathermy on vegetables were not of much use for deducing principles in regard to a patient's living tissues It had not been the experience at St Bartholomew's Hospital that broncho-pneumonia often developed afterwards He thought diathermy ought to receive a thorough trial in the treatment of carcinoma of the cervix Dr Henry, of Omaha, preferred diathermic coagulation in early cases of carcinoma of the cervix to hysterectomy By using the proper technique burns could be avoided, whilst ligation of arteries prevented secondary hæmorrhage

Mr Steward, in a brief reply, said he was glad his pessimism about the use of diathermy in lesions of bone was apparently not well founded The general situation, good as it already was, could be expected to improve yet further with careful observation and better technique

---

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF MEDICINE

A meeting of this Section was held on Dec 3rd, Dr G E Nesbitt, the President, in the chair

Dr R H Micks and Dr W R Fearon described a case of

Hæmatoporphyrinuria

They stated that the urine was a deep port-wine colour and showed no absorption bands By adding 10 per cent barium chloride solution, drop by drop, to boiling urine the pigment was carried down with the precipitate of barium salts, and removed from the precipitate by extraction with glacial acetic acid, or with a 5 per cent solution of sulphuric acid in 90 per cent alcohol

Dr R R Leeper said that the patient from whom the urine was obtained was a man who had been under his care for some years He suffered from dementia præcox, and was cyanosed in the extremities One night he suffered from retention of urine , Dr Leeper drew off the urine, and found hæmatoporphyrinuria The patient had had no drug treatment

Dr L Abrahamson said that he assumed the hæmatoporphyrinism in this case to be of the acquired variety, as the cause was not apparent He referred to four cases he had reported in the *Quarterly Journal of Medicine*, two of which were of the acquired type, and two congenital

Dr A R Parsons referred to a case of hæmatoporphyrinuria described by him in 1906

The patient, a woman of 23, complained of very severe abdominal pain, constipation, and sleeplessness, for which there was no apparent cause The urine was generally normal when passed, but later changed colour and became the colour of port wine The patient had had no drug treatment whatsoever She recovered and left hospital, but about a month later she returned much worse She developed symptoms of peripheral neuritis, and died some time later Alkalis were given freely, but without any benefit

Dr W M Crofton and Dr Preston Ball joined in the discussion

Dr E T Freeman described a case of

Chronic Gastric Ulcer

The patient, aged 45, was a professional man who for seven years had had abdominal pain, which was worse in the summer and early autumn, when he was in the habit of eating much fruit In September, 1925, the pain had been more severe than usual, and he complained of pain over the ensiform cartilage and inability to walk, stand, or sit up without discomfort There was slight tenderness in the mid-line, but the gall-bladder was neither tender nor palpable The patient looked slightly jaundiced, and had bradycardia (pulse-rate 58) The teeth were excellent, and there was no obvious infection of tonsils A fractional test-meal showed hyperchlorhydria and some leucocytes and blood-cells A radiogram showed an ulcer on the lesser curvature, with a large crater towards the pancreas, slight pylorospasm, and duodenal irregularity The urinary diastase was 8 units, and the van den Bergh test gave a very faint indirect reaction not more than normal

The ulcer, said Dr Freeman, was of the type for which surgical intervention was usually suggested, and for which gastro-enterostomy would be useless, as the pylorus emptied normally The patient was put on a rigid diet—milk and cream every hour, with alkaline powder between, and ℞ xx of tincture of belladonna ex aqua each night Eggs, ground rice, bread-and-butter, and vegetable purées were gradually added At the end of three weeks he was allowed fish, and was then taking three small meals daily, with milk and cream and alkalis between He had now been on an almost normal diet for some months, with alkaline powder and cream mixture He was not allowed to eat a greater total quantity than 12 oz at any meal Radiograms taken during October and November showed no ulcer, and the patient had had no symptoms since the second day of treatment Great credit was, however, due to the patient for his complete cooperation The aphorism attributed to Sir J K Fowler that no fool was ever cured of pulmonary tuberculosis might be applied to gastric ulcer

Dr Micks referred to a paper by Einhorn and Crohn, of New York, describing 101 cases of gastric ulcer treated medically during the last four years They stated that after a year about 80 per cent appeared to be cured, but that after four years only about 50 per cent of the cases treated had not relapsed He thought that in the average working-class patient this was the most that could be hoped for

Dr J H Pollock read a paper entitled

Observations upon Scarlatina

He discussed the frequency of hæmolytic streptococcal infection, as shown by blood cultures and metastatic abscess formation He believed that a streptococcal septicæmia was very frequent

The President said that he had used antitoxin to some extent at the Richmond Hospital, but it was expensive, and he could not say that it had had any remarkable effect in his cases—nothing at all comparable to the effect of diphtheria antitoxin

Dr Crofton said that English workers had for years maintained that a streptococcus was the cause of scarlatina

Dr W E Hutchinson said that he had been at Cork Street Hospital for a year while cases of scarlatina were being treated on the ordinary lines After that time the use of serum had come in, and he had no doubt from a comparison of the results that serum should be used. He mentioned one case which on admission had been absolutely comatose 10 c cm of serum were given that night, and the same amount the next morning recovery was uninterrupted He could not be sure whether the giving of serum lessened the complications that arose in cases of scarlatina

Dr R J **Rowlette** asked if all the cases treated were cases of true scarlatina, or if they were cases of sepsis simulating scarlatina It was important to make a definition between cases of true scarlatina and cases of acute sepsis with a rash He asked if the use of vaccines made from the organisms which were separated from the blood had been tried He thought that probably an autogenous vaccine would be more helpful than serum, and that vaccine and serum together would be more helpful than either serum or vaccine used alone

Dr **Pollock**, in replying said that they had found at Cork Street Hospital that the giving of serum did not make any difference regarding the length of time of convalescence He thought it possible that, as time went on, scarlatina would be regarded much less as a separate entity than it had been considered recently he also thought that the nomenclature of many of the fevers would be changed in the future

Dr W G **Harvey** showed a case of lichen planus acuminatus and lichen annularis

Dr **Abrahamson** read a paper on the diagnosis of coronary thrombosis and a discussion followed

EDINBURGH OBSTETRICAL SOCIETY

A meeting of this Society was held on Dec 8th, Prof R W **Johnstone**, the President, being in the chair

Prof J A **Kynoch** described two cases of

Rupture of Uterus following Cæsarean Section

The two cases, he said, had been met with within two months

Case 1 —The patient had had two Cæsarean sections, and was again nearly at full term The clinical features were severe collapse, preceded by several hours of abdominal pain and sickness, during which time the patient had walked several miles in search of work Operation was performed immediately on admission, and an aperture about the size of a five-shilling piece was found at the lower end of the scar, which was thin and translucent for its whole length, the peritoneal coat being alone intact There was a considerable quantity of free blood in the peritoneal cavity Supravaginal hysterectomy was performed, and the patient left hospital three weeks after admission

Case 2 —The patient also was eight months pregnant, and had had one previous Cæsarean section. She was suddenly doubled up with pain, and had a fast pulse and hurried respirations, the rupture being complicated by an acute lobar pneumonia Rupture was diagnosed and the abdomen opened under local anæsthesia The rupture was found to be five inches in length and the membranes bulged through After removal of a dead child, the wound was sutured and the patient sterilised After a somewhat stormy convalescence, owing to the chest condition, the patient eventually did well, and was discharged four weeks after operation

Prof Kynoch went into the statistics of rupture after a previous Cæsarean section, and contrasted the results of the classical and lower uterine segment incisions The most frequent causes of rupture, he said, seemed to be infection with defective coaptation of the wound edges, the use of catgut as a suture material, and attachment of the placenta to the line of the incision Both of his cases had had a febrile convalescence at the previous Cæsarean section, and in each case catgut had been employed Prof Kynoch favoured silk as a suture material for Cæsarean sections, and thought catgut very unsuitable

Dr C G **Lambie** read a paper on

Diabetes and Pregnancy,

which were rarely associated, he said, because diabetes caused atrophic and sclerotic changes in the ovaries and uterus, with resulting sterility, disorders of menstruation, and sexual frigidity These functional disturbances could often be rectified by the use of insulin, except where organic changes were advanced, as in the more chronic cases.

Referring first to the effect of pregnancy upon diabetes Dr Lambie said that pregnancy exacerbated pre-existing diabetes, and might be the starting-point of the malady in predisposed individuals The factors leading to deterioration of sugar tolerance were (1) absorption of products of protein hydrolysis from the placenta during the first three to four months—a condition analogous to infection, (2) the emotional excitability of the earlier months, causing glycogenolysis in the liver, (3) over-eating, after the period of morning sickness was over, (4) the necessity for giving a good deal of carbohydrate to prevent acetonuria. (5) hyperactivity of the thyroid and pituitary glands during the later months. Improvement in tolerance was commonly observed towards the end of pregnancy, while simultaneously an increasingly large amount of carbohydrate was utilised by the fœtus The islet tissue of the fœtus underwent marked hyperplasia and hypertrophy to meet the increased functional demands There was no good experimental evidence that insulin passed from the fœtus to the mother During labour the blood-sugar rose slightly, but after delivery there was a sharp rise, the hyperglycæmia lasting for 24 to 48 hours Thereafter an improvement in tolerance occurred and might be accompanied by hypoglycæmia in cases treated with insulin This was due either to a return of pancreatic function, or to excretion of carbohydrate as lactose on the milk, or to replenishment of the glycogen reserves after their depletion during labour, in which case it might be quite short-lived and was followed by another fall in tolerance, after which there might be gradual improvement. Acetonuria during labour was due to depletion of the glycogen reserves in order to provide carbohydrate for the supply of energy for muscular contraction or to anæsthetics, starvation, hæmorrhage, or sepsis After delivery, the tendency to acetonuria disappeared, more fat could be taken, and the necessary calories might be given with a smaller intake of glucose

Turning next to the effect of diabetes upon pregnancy, Dr Lambie said that both maternal and fœtal mortality were high Hyperglycæmia in the fœtus, which was secondary to maternal hyperglycæmia, resulted in hydramnios, the development of an excessively large fœtus, and hyperplasia of the islets of Langerhans in the fœtal pancreas Hydramnios might be caused by fœtal diuresis together with endosmosis, due to high osmotic pressure of the saccharine fœtal urine Hypoglycæmia, due to excessive insulin secretion by the hyperplastic islet tissue, was a possible cause of death after birth These conditions, with their associated obstetric complications, were avoided by the use of insulin Insulin also raised resistance to infection and diminished susceptibility to puerperal sepsis

Diabetes he continued, had to be distinguished from other forms of glycosuria occurring in pregnancy—namely, early alimentary glycosuria, renal glycosuria, lactosuria, glycosuria due to carbohydrate starvation, and late alimentary glycosuria The last might closely resemble diabetes, and was liable to similar complications Its most outstanding feature was its rapid disappearance within about 10 days of delivery It was probably of hypophyseal origin In some cases hyperthyroidism might be a cause of glycosuria Insulin had improved the prognosis, especially as regards the life of the mother Some cases now passed through pregnancy without loss of tolerance, pregnancy might go on to full term and a healthy child might be born The diet must contain a relatively high proportion of carbohydrate in order to avoid acetonuria After delivery a high-fat low-carbohydrate diet might be given, and it then became possible to reduce or abolish the dose of insulin The caloric requirements were about

35 calories per kg. per diem, and the protein minimum was approximately 1·2 g. per kg. per diem. Insulin was administered in the usual way, and did not harm the fœtus even when minor attacks of hypoglycæmia occurred.

Induction of abortion was indicated, said Dr. Lambie in conclusion, (1) where diabetes had existed prior to pregnancy and the patient was unwilling to submit to continuous supervision under suitable conditions; (2) in very emaciated, ill-nourished subjects; (3) where there was rapid loss of tolerance in spite of treatment; and (4) in cases of acidosis with uncontrollable vomiting. Where a large fœtus was expected premature labour might be induced, or Cæsarean section under nitrous oxide and oxygen anæsthesia might be performed. Labour was best conducted under hyoscine and morphine narcosis. During labour usual doses of insulin together with a very liberal allowance of easily assimilable carbohydrate, should be given to prevent acidosis.

Reviews and Notices of Books.

TREATMENT.

The Elements of Medical Treatment. By ROBERT HUTCHISON, M.D., F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street, London. Bristol: John Wright and Sons, Ltd. 1926. Pp. 163. 7s. 6d.

Principles of Medical Treatment. Sixth edition, revised and enlarged. By GEORGE CHEEVER SHATTUCK, M.D., A.M., Assistant Professor of Tropical Medicine, Harvard Medical College. Cambridge: Harvard University Press. London: Humphrey Milford, Oxford University Press. 1926. Pp. 252. 15s.

IT is admittedly difficult for the student in the wards to learn much about treatment; most of his time is occupied with case-taking and diagnosis, and if he is really interested in treatment he has to consult large volumes. Dr. Hutchison's excellent book should remove some of his difficulties, for it sets out in elementary form the basic principles of treatment and their application to the commoner types of disease. An introductory outline in 11 pages contains more wisdom than many a large text-book of therapeutics. Then follow chapters devoted to such subjects as fever, pain, insomnia, constipation, &c., and after this certain definite diseases such as nephritis, bronchitis, pneumonia, &c., receive attention. A chapter on psychotherapy has been written by Dr. T. A. Ross; sections on diabetes and the use of insulin and an account of some minor medical operations are contributed by Dr. Devereux Forrest. Throughout the book prescriptions are not only set out in full, but also each ingredient is clearly explained, and the advice given in the introduction "to use only a few drugs but to know them and their effects intimately," should be easy to follow if this book has been intelligently read. It should make a wide appeal to students, resident medical officers, and young practitioners for the advice it contains is sound, free from fads, and not overburdened with useless detail.

In its sixth edition Dr. Shattuck's book has been considerably enlarged and revised, many authors now contributing special sections. The chapters on asthma, syphilis, lead poisoning, anæmia, endocrine disturbances, pre-operative and post-operative medical treatment, and on vaccine therapy are entirely new. Dr. Shattuck is also a firm believer in the habitual use of only a few drugs; and in a masterly chapter on medication he sets out two lists, the first containing 11 "very valuable drugs," and the second some 15 groups of "useful drugs." The 50 pages which make up this chapter are as valuable as the whole Pharmacopœia. English readers should not be put off by the fact that the references are mostly to official and non-official American preparations, for this does not affect the value of the advice offered.

RHEUMATISM: ITS MEANING AND ITS MENACE.

By LEWELLYS F. BARKER, M.D., and NORMAN B. COLE, M.D. London and New York: D. Appleton and Co. 1926. Pp. 165. 5s.

IN this little volume an attempt has been made to present to the public the facts about all forms of arthritis (including gout) as they are, however imperfectly, known to the medical profession. The book supplies a good summary of the subject; the practitioner also will profit by its perusal because it will fortify him anew against the employment of pseudo-scientific theories in treatment, upon which intractable cases are always tempting him to rely. Two of the first three chapters deal with rheumatic fever and its complications laying stress, of course, upon the preventability of rheumatic carditis as a national disease. A word should here be said as to the use of the word "infectious," which American writers apparently use as synonymous with our word "infective," as applied to this disease. Chronic arthritis is subdivided into (1) chronic infectious (i.e. infective) arthritis, (2) chronic progressive polyarthritis; and (3) primary hypertrophic osteo-arthritis. These conditions are described in detail in three successive chapters. Primary hypertrophic osteo-arthritis is stated not to be "a sequel of infection in other parts of the body in the same sense as" are the other two forms. The next chapter is about treatment of all three forms in all of which the removal of any infective cause and the prevention of crippling processes are put forward as the ideal. Drugs are not considered by the authors to be efficacious in any specific way, and hot water is stated to be the cause of the favourable reports from spas. The fads of dietotherapists are to be discouraged, and a commonsense mixed diet under the supervision of the family doctor is advocated. No alleged short cuts to cure are credited by Dr. Barker and Dr. Cole, who write with a real sense of professional responsibility. A chapter on gout is followed by another pointing out the social significance of the rheumatic diseases in general; it is noted that as a result of these diseases over 60,000 work-years are lost annually in Britain. A glossary is added for the convenience of the layman. As an experiment in education of the laity this book is of special interest. It will be instructive to learn whether it goes through many editions during the next few years or suffers in popular esteem from the absence of the plausible but wholly unscientific hypotheses which are so often the mainspring of books designed for the general public. We wish it success.

AVIATION MEDICINE.

By LOUIS HOPEWELL BAUER, A.B., M.D., Major, Medical Corps United States Army; Commandant, The School of Aviation Medicine. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1926. Pp. xvi + 241. 34s.

THIS book is divided into three main sections: I. The Selection of the Flyer; II. The Physiology of Aviation including the Classification of the Flyer; III. The Care and Maintenance of the Flyer. A supplement gives detailed instructions for certain tests and forms of examination in use by the U.S. Army and Navy Air Services and a comprehensive bibliography is included. In Section I. the general physical qualifications required in an aviation candidate are set out, special reference being made to the eye, ear, nose, and throat. Neuropsychic factors and reaction times are considered in detail. Section II. deals with the effects of altitude upon the heart, respiratory, circulatory, and nervous systems and various altitude tests which have been devised are discussed A chapter on the Effects of Wind, Cold, and Speed concludes this section Section III has chapters on Fatigue, Staleness, and Physical Fitness Protective Devices, Duties and Training of the Flight Surgeon, Aviation Accidents, Dope Poisoning and Civilian Flying

The author insists on the desirability of a separate medical service consisting of specially trained medical officers for an air service He points out that the medical officer associated with this service needs a considerable amount of training He has to learn to conduct the selection examination, to carry out the altitude test, and to superintend the maintenance of physical and mental health of the airman from his knowledge of the possible effects of a peculiar environment The standard of normality demanded of airmen in America is evidently not very high For example, the advisability of accepting a candidate for flying who has " at least 75 per cent mobility of the knee-joint, 50 per cent mobility of the ankle-joint " is open to doubt A candidate suffering these degrees of limitation of joint movement would probably not be able to keep himself fit by taking part in games and exercises, the necessity of which is rightly stressed in a later chapter In the consideration of blood pressure in a candidate the systolic pressure alone is here mentioned, nothing is said of the significance of the pulse pressure, which is considered by many to be of greater importance

It is clear that there is still much work to be done in the assessment of fitness for flying, particularly in regard to reaction time tests and the effects of high speeds upon the airman His ability to appreciate changes of motion from one plane to another is an important point difficult to estimate Major Bauer has marked out clearly the ground that will have to be explored, and his modest volume is likely to be the forerunner of a considerable mass of literature as our knowledge increases

Surgical Treatment in Ophthalmology

Therapeutique Chirurgicale Ophtalmique By Prof C Duverger (Strasbourg) and Prof E Velter (Paris) Paris Masson et Cie 1926 With 40 plates, mostly coloured Pp 180 18*s.* 4*d*

Some six years ago[1] we reviewed a book in which Dr Duverger advocated local anæsthesia by deep injection into the region of the nerves supplying the part with sensation, for enucleations and nearly all intraocular operations in which the instillation of drops is insufficient, deep injection into the region of the ciliary ganglion was recommended He and his collaborator now lay further stress on the advantages of this technique, and fully explain its detailed application in all lid and plastic operations, in excision of the lacrymal sac when injection of the infraorbital nerve canal as well as the nasal nerve is performed, and even in such major operations as the removal of retro-ocular orbital tumours General anæsthesia, they declare, has scarcely a place in ophthalmic surgery, almost the only patients for whom it is called for being young children and cases of grave infection such as orbital abscess They contend that inflamed eyes can be rendered completely insensible by their methods As this doctrine is contrary to that generally taught in this country, this section alone makes the book worthy of study by ophthalmic surgeons The other sections are no less interesting, the illustrations being throughout excellent Descriptions of innumerable lid operations are often wearisome or difficult to follow, but here the number of operations described is strictly limited, and the illustrations make the accounts abundantly clear The authors do not profess to include all the operations of ophthalmic surgery but merely the ones which they themselves recommend or have adopted For instance, we can find no reference to " epithelial inlays " and " outlays " for plastic operations to intracapsular extraction of cataract either by Smith's or by Barraquer's method, and to many other operations which might have been included On the other hand, such unusual and difficult procedures as amputation of the anterior segment of the eye, exenteration of the orbit and the formation of a new socket for an artificial eye are fully illustrated The views expressed are individual but none the less interesting No operation is described for conical cornea, because the authors do not recommend any For glaucoma the operations of Lagrange and Elliot (spelt " Elliott ") are both illustrated, and, as is perhaps to be expected in a French book, the former is recommended as on the whole the better though not the easier As a supplement to enucleation the implantation of a glass ball is condemned, while that of a piece of ox's cartilage is recommended The book may well find a place on the shelves of any ophthalmic surgeon in England who desires to keep up with the best foreign work in his specialty

Retrobulbar Neuritis of Nasal Origin

Rhinogene Neuritis Retrobulbaris By Prof Dr J Meller, Chief of the University Eye Clinic, and Dr Oscar Hirsch, Tutor in the University, Vienna Berlin S Karger 1926 Pp 62 M 1 80

Dr Meller's object in writing this essay is to maintain the thesis that retrobulbar neuritis can be caused by so slight or evanescent a grade of inflammation in the accessory sinuses of the nose as to show to the rhinologist no sign of disease, even on the most thorough examination He believes further that, in disseminated sclerosis, the special susceptibility of the optic nerve is caused by its proximity to the accessory sinuses and, therefore, that the retrobulbar neuritis of this disease is in reality of nasal origin It follows that he insists on rhinological treatment, in the absence of all signs of intranasal disease, in cases where a most careful examination of every possible cause has been fruitless Treatment is not necessarily operative, for he quotes Herzog's recommendation of " continuous ischæmia " of the nasal passages, obtained by applying adrenalin-soaked pledgets of cotton-wool to the middle meatus every two hours, instancing the case of a 22-year old girl with left-sided retrobulbar neuritis, stationary for three weeks, who recovered after applications twice daily for three days Dr Hirsch devotes a large part of his contribution to other orbital complications of sinus disease, but his main object is to support Dr Meller's thesis He refers to cases in which the mucosa of the ethmoid was found at operation to be œdematous, although the nasal passages appeared perfectly healthy, and to others where microscopical examination of the mucous membrane lining the sinuses showed inflammation, although it seemed macroscopically to be normal

Although it is possible that the authors do not allow sufficient weight to the numerous cases of retrobulbar neuritis which recover spontaneously, their arguments are well marshalled and deserve attention from oculists and rhinologists alike

Diseases Associated with High Blood Pressure

Die Hypertoniekrankheiten By Dr Eskil Kylin, Director of the Military Hospitals and of the Inpatient Departments of the District Hospitals, Eksjo, Sweden Berlin Julius Springer 1926 Pp 168 Mk 8 40

During the last nine years Dr Kylin has been working on blood pressure and its variations in renal disease, and on changes in amount and composition of the blood in diseased states All the important evidence derived from these studies and those of numerous other writers, is collected in this compact book Kylin calls attention especially to recent advances in our knowledge, and shows how our whole conception of the subject of blood pressure is being revolutionised by new work on capillary tension, peristaltic action in the capillaries, and glomerulonephritis He discusses the methods of estimating arterial blood pressure and its normal variations and gives a table of the average blood pressures in the various decades of life, based on a large number of cases According to this table, the average arterial blood pressures between the ages of 15 and 40 vary only between 115 mm and 121 mm, and the average maximum systolic pressure between 132 mm and 170 mm for the same period Two methods of measuring capillary pressure are described The first is a bloodless method, using a convenient manometer devised by him, which is light to handle and can be used with any microscope The other method consists of tubes of known calibre into which the blood is allowed to flow from the capillaries The results of the author's investigations of the capillary pressure in the prenephritic stage of so-called acute glomerulonephritis lead him to the conclusion that this disease is primarily vascular, this conception has not yet received general acceptance An important section of the book is devoted to "Essential Hypertonia," symptomatology, and variations in the blood calcium potassium cholesterin, and adrenalin being set out The last chapter is concerned with the ætiology and symptoms of permanent hypertonia Throughout the book Dr Kylin tends to emphasise ætiology and pathogenesis rather than treatment, short discussions of the prevention of acute glomerulonephritis by treating sources of infection, and of the treatment of permanent hyperpiesis by diet and other methods are, however, included

[1] The Lancet, 1920, ii, 355

The Abdomen in Labour

By NORMAN PORRITT, M R C S, L R C P Lond, Consulting Surgeon, Huddersfield Royal Infirmary London Humphrey Milford, Oxford University Press 1926 Pp 76 5s

THIS little book is a reprint of the essay which was awarded the Sir Charles Hastings clinical prize of the B M A in 1926 The prize is awarded for work carried out by a general practitioner In his essay, the chief object of the author is to point out the advantages of abdominal over vaginal examinations for diagnosis, during labour, and in this he succeeds admirably Particularly good are the remarks on inspection of the abdomen There are a few obvious errors, much of the argument used in favour of the dorsal position appears illogical, and the illustrations are rather difficult to understand, but the book contains much that should be useful both to teachers and students

Physical Chemistry in Biology and Medicine

By J F MCCLENDON, Ph D, Professor of Physiologic Chemistry at the University of Minnesota Medical School, and GRACE MEDES, Ph D, Assistant Professor of Physiologic Chemistry at the School London and Philadelphia W B Saunders Company 1925 Pp 425 21*s*

THIS volume is divided into two sections, "Physico-Chemical" and "Physiologic" Part I opens with a three-page chapter on the concept of mass, followed by a five-page account of the structure of the atom Of these five pages two are taken up with diagrams and two with tables The net result is a wholly unintelligible summary of mass and the atom The other chapters of this section are not much better In the second section the first chapter is entitled Radiant Energy In eight and a half pages the nature of radiant energy, the quantum theory, photosynthesis, actinotherapy, and bioluminescence are dealt with The reader is then led through atomic structure and physiological action thermo-chemical considerations, colloids, and ionic equilibria in blood in quick time The recent nomograms of L J Henderson are included in the last-mentioned section The authors' knowledge of the literature, and particularly of out-of-the-way publications, is evidently great, and it is regrettable that this work, which must have caused them considerable labour, gives such a disjointed picture as to be unreadable Physical chemistry has never been a popular subject with medical workers, and a study of this book is not unlikely to turn them from it for ever Not only the paragraphs, but even the sentences lack continuity The authors pass from erythrocytes abruptly to sea-urchins' eggs, jumping off to the freezing-point of various types of coctus, with the result that a state of mental nystagmus is produced in the reader's mind

The Origin of Man.

The Pedigree of the Human Race By H H WILDER Ph D London · G G Harrap and Co 1926 With 113 figures Pp 368 12*s* 6*d*

THE author of this book is professor of zoology in Smith College, Massachusetts He gives us here a plain and very readable account of what we know and what we may surmise of the ancestry of the species *Homo sapiens* and of its several varieties The suborder anthropoidea of the primates includes Tarsius (the little nocturnal arboreal animal from the East Indies, of which so much has been lately made in the discussion of human origins) the marmosets, the ordinary monkeys, and finally the family Hominidæ which contains the gibbons and siamangs, the higher apes, and man Prof Wilder is firm in stating that there are no grounds more valid than human pride and prejudice for separating man into a different zoological family from the orang-outans, gorillas, and chimpanzees One is surprised to learn how much of the detailed anatomy of these apes is still unknown, and the detailed dissection of the different varieties of man is a promising field, which needs exploration Of extinct forms we have *Homo neanderthalensis* (which Virchow thought was a deformity, but whose existence as a constant type has now been fully established) and *H heidelbergensis* as species of man, and Du Bois's *Pithecanthropus* from Java, Dart's *Australopithecus* from South Africa, and the Piltdown *Eoanthropus*, representing the human strain or something near it after its divergence from the line which has led to the apes The book illustrates one aspect of zoological progress which is apt to cause difficulty to those who are not specialists, though Prof Wilder tides us gently over the changes of names which terminological exactitude requires; the gorilla is still *Gorilla*, but the orang-outan is *Pongo*, and the chimpanzees are *Pan* The names are in themselves so attractive that we are reconciled to them as easily as we can take to calling *Amœba proteus* by the name of *Chaos diffluens* It is to be hoped that the author will be able to find Miss Harriet Andrews, she certainly deserves to be thanked for the charming picture on p 76

Goiter and Other Diseases of the Thyroid Gland

By ARNOLD S JACKSON, M D, Jackson Clinic, Madison, Wis London · Humphrey Milford, New York Paul B Hoeber 1926 Pp 401 50*s*

THIS very complete book is written mainly from the point of view of American work, but can confidently be recommended as an up-to-date presentation of the subject The author disagrees with the theory that colloid goitre represents the resting stage of the gland following stages of hypertrophy and hyperplasia, like Plummer he believes that colloid goitre represents an active stage of the gland, and arises because under certain circumstances—i e, during rapid growth, the thyroxin in the tissues becomes exhausted Consequently the gland becomes overworked in trying to make up the deficiency, and lags behind the demands of the body for thyroxin, secreting colloid, which is stored in large quantities The author, of course, advocates operative procedures for toxic goitre, and the detailed description of his technique is one of the most valuable parts of the book, but a very useful chapter on substernal thoracic goitre is given, and its diagnosis by X rays is illustrated Plummer's treatment of hypothyroidism by intravenous thyroxin in doses short of 15 grains (the normal quantity in the body) is described Dr Jackson points out that by oral *administration alone it is impossible to make up the* loss that the body has sustained The book is largely a compilation of other people's experiments and results In a monograph on this subject by a prominent worker we would have expected his own cases to have been considered in rather greater detail The book might quite well have been condensed and the bibliography further enlarged, since several authors are mentioned in the text to whose work no reference is given The photographs of patients and of pathological and microscopical material are good

---

SYNTHETIC ANATOMY.

By J E CHEESMAN Part I, The Upper Arm and Shoulder, II The Forearm, *III*, The Hand London Baillière, Tindall and Cox 1926 Each Part with index and instructions 2*s* 6*d*

THIS is a new and ingenious presentation of anatomical details by a series of transparencies, accurately adjustable on each other, which thus afford a complete idea of the limb built up on its skeleton Conservatism may lead a teacher to look askance at seemingly iconoclastic methods of inducing the student to grasp and remember the *relations of the structures with which he deals*, but these pictorial transparencies deserve careful examination We know of students who have found much help from them, and on general principles any reliable method of instruction which might make the learner think of anatomical structure in terms other than those of formal description is to be welcomed, too many students look on anatomy as the subject of a book, rather than as the structure of the body The *drawings are pleasing, especially* where the skeleton comes into the exhibited plane The treatment is conventional, in the sense that there is no claim to represent actual dissection, and such things as subcutaneous vessels and nerves are shown in purely schematic manner We *have found no errors* in the presentations, though the amount of detail given is surprising The upper limb only has *appeared* so far, the hand being of natural size, the student can enlarge the whole or part of any drawing, or make use of any combinations he pleases The transparent media, colours, and adjustments are excellent, and each index is given in both terminologies The issue of the remaining parts will be awaited with interest

---

Reports and Analytical Records.

PARA-THOR-MONE LILLY

(ALLEN AND HANBURYS, LTD, BETHNAL GREEN, LONDON, E)

PARA-THOR-MONE is an active extract of parathyroid glands of cattle prepared, under the authority of the University of Alberta, according *to a method* elaborated by Prof J. B Collip It is a stable aqueous solution *of the active* principle (or principles) standardised by its capacity to increase the total blood-serum calcium in normal dogs One unit is defined as one-hundredth part of the dose required to cause an increase of 5 mg of calcium in the blood serum of a 20 kg dog, 15 hours *after injection* Para-thor-mone is regarded as a true specific in cases of tetania parathyreopriva, and has relieved the symptoms of idiopathic and infantile tetany Its use has been attended with beneficial results in some cases of arterial hypertension, in tropical sprue, and in the treatment of chronic ulcers and ulcerative colitis; it has been tried in chorea, epilepsy, and conditions of protein sensitisation, such as asthma and hay-fever In clinical cases as much as 100 units have been given in 24 hours without ill-effect, but such a dose is unnecessarily large and should not be continued or repeated daily In cases of well-marked tetany relief may be expected from 20–30 units, repeated two or three times within the first 24 hours and then diminished Doses ranging *from 10–25 units daily* have been found to prevent recurrence of tetany in the chronic form of the condition In *infantile tetany a dose of 10 units* is advocated Para-thor-mone, Lilly, may be given subcutaneously, intramuscularly or intravenously, and is supplied in 5 c cm rubber-capped ampoule-vials containing 100 units

ACETYLARSAN.

(WILCOX, JOZEAU AND CO, 15, GREAT ST. ANDREW-STREET, LONDON, W C)

Acetylarsan, as prepared at the Usines du Rhône, is an aqueous solution of a substitution product of benzene containing 23 6 per cent of oxy-acetylaminophenylarsinate of diethylamine, and is regarded by a number of French authorities as a spirillicide practically equal in activity to arsenobenzene The substance was chosen in the course of a search *for an arsenical compound of high physiological activity*, tolerated locally by the tissues, acetylarsan can be injected either beneath the skin or into the muscles without causing any pain whatever Laurent, Chatelier, Gougerot and Lacapère, among others, have conducted tests under controlled conditions showing immediate disappearance of the treponemata after administration of this drug, rapid evolution of the cutaneous phenomena *and characteristic* serological reactions The solution, which is neutral, colourless and limpid, contains arsenic in the proportion of 0 05 g per c cm The dose tolerated by mice is 20 cg per kg, by rabbits 40 cg For a man of average weight a dose of 1 15 g may be administered in one injection without adverse reaction except in rare cases of idiosyncrasy Elimination is rapid, often being complete in 36 hours, so that bi-weekly *injection is possible if desired* A trial injection of 1 or 2 c cm is recommended before the weekly injections of 5 c cm are commenced, and the usual course lasts eight to ten weeks, by the end of which time 10 g of the salt will have been given Herxheimer's reaction is practically unknown, but *there* may be nausea and possible vomiting 6–8 hours *after the injection, and occasionally a* slight brief rise in temperature In the ordinary way the injections do not interfere with ambulatory treatment Acetylarsan is supplied in boxes containing 10 ampoules each of 3 c cm A solution known as "infantile acetylarsan" is also supplied two and a half times weaker than the ordinary solution.

THORNE'S EXTRA SUPER CRÊME TOFFEE

(HENRY THORNE AND CO, LTD, THE COCOA WORKS, LEEDS)

We have received for examination samples of this toffee which is sent out in convenient sized pieces weighing above five to the ounce, each piece being separately wrapped in greaseproof paper Analysis *showed the following composition* —

Water	4 40	per cent
Total ash	1 92	„
(Containing salt)	0 77	„
Fat	23 50	„
Protein	2 60	„
Sugar	67 58	„
	100 00	„

Calorie value per lb 2204

This is a pure and palatable sweetmeat and contains somewhat more sugar than the older fashioned toffees of the Everton type The salt present is very small in amount, and those who prefer *this type* of toffee will find it an excellent one of its class

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them

XXVI —CASES OF POISONING AND SUSPECTED POISONING.

By G Roche Lynch, O B E , M B ,
B S Lond , D P H ,
OFFICIAL ANALYST TO THE HOME OFFICE, DIRECTOR OF THE DEPARTMENT OF CHEMICAL PATHOLOGY, ST MARY'S HOSPITAL, LECTURER ON FORENSIC MEDICINE AT WESTMINSTER HOSPITAL

One of the most harassing predicaments of medical practice is the occurrence of some incident which leads to the suspicion that a patient is the victim of foul play—whether by interference with the treatment prescribed or by the addition of poisonous substances to food or medicine Many suspicions of this sort are totally incapable of proof and, indeed, turn out to be entirely unjustified Nevertheless, many practitioners of long standing can recall occasional cases where subsequent events have not served to abolish their doubts Homicidal poisoning in this country is rare when contrasted with some tropical countries, such as India, but it must be remembered that the criminals are not always brought to justice The intimate relations of the medical man with the patient and the household place him in an unrivalled position for close observation of suspected cases, and he is sometimes able to avert tragedy.

Statistics of Homicidal Poisoning.

From statistics of homicidal poisoning the following points stand out (1) The motive is generally of domestic, passionate, or greedy origin (2) 30 per cent of homicidal poisoning occurs in towns and 70 per cent. in country places This need not be taken to imply that there are more criminals of this type in rural districts, but rather that he is more likely to be found out, since his private affairs are known in greater detail by his neighbours In other words, the poisoner stands a greater chance of successfully evading detection in town than in the country. (3) Successful poisoners often have more than one victim to their credit (4) Mostly the crime is *premeditated*, and often great craftiness is displayed (5) Far more males commit crime than females, but the percentage of females using poison is greater than males (6) The fact that often homicidal poisoning is only discovered after an exhumation has been made, the original burial order having been granted on the authority of a medical certificate of death, shows the difficulties and responsibilities of the medical practitioner

What is a Poison ?

Poisoning may occur as a result of one of the four following circumstances (1) Administration for homicidal purposes (2) Self-administration for suicidal purposes (3) Self-administration for a special purpose —e g , abortion (4) Accidental administration

Before discussing these possibilities in detail it is pertinent to inquire what, *from the* forensic standpoint, constitutes a poison It is, however, the *intention* to murder or harm which constitutes the crime; consequently the administration of substances not usually regarded as poisons may be poisons from the legal point of view if they are administered with evil intention The sections of the Acts relating to poisoning determine the nature of the offence according to whether murder, grievous *bodily* harm, or injury or annoyance was intended The law makes use of a variety of expressions such as poison, noxious thing, destructive thing, stupefying or overpowering drug, matter, or thing in order to make the statutes as comprehensive as possible For example, 24 & 25 Vict ch 100, sec 11, reads: "Whosoever shall administer or cause to be administered or taken by any person any poison or other destructive thing with intent to commit murder shall be guilty of felony." In the section dealing with the administration of chloroform, &c , for stupefying, whereby a felony can be committed, the words used are "chloroform. laudanum or other stupefying or overpowering drug" ; in the statute dealing with abortion the words are "poison or noxious thing" Various judicial decisions, although clearing the legal position, have thrown great responsibility on the medical witness. It has been laid down that (1) there must not only be an administration of a noxious drug with guilty intent, but it must have been administered in sufficient quantity as to be noxious ; (2) if a person administers with intent (in the particular case in which the ruling was made "to procure the miscarriage") something which as administered is noxious, he administers a "noxious thing" A distinction is to be drawn between a thing that is only noxious when given in excess and one which is recognised as a poison and known to be noxious and pernicious in its effect. The law does not make any distinction regarding the mode of administration Administration hypodermically, by mouth, per rectum, or elsehow, of a poison with intent to murder or injure are punishable felonies The only question that will be raised is whether the substance dealt with is noxious Similarly also the admixture of cultures of micro-organisms or their toxins are equally poisons and have the same significance The medical witness will have to decide whether a substance was noxious and whether it was given in excess, and into this consideration the age, health, tolerance of the victim will enter, and repeated administration of small doses may have to be considered

The words grievous bodily harm require elucidation. It has been defined as the infliction of an injury which seriously interferes with health or comfort or both. It need not be permanent or dangerous

How to Investigate a Suspected Case

The method of approaching an investigation, when, from information received from a second person or from personal observation, suspicions are aroused that foul play may be occurring, require careful consideration Suspicions, once aroused, soon assume formidable dimensions unless each incident is critically examined and a natural explanation sought, and rarely are they subsequently justified During the two years subsequent to the mention of poisoned chocolates in the case of R *v* Armstrong numbers probably running into hundreds of samples of chocolates were submitted to analysts in this country alone , in only two or three cases was poison found, and in those cases the methods of tampering with the sweets were of the crudest nature

When poisoning is suspected the physician should attempt to take apparently motiveless steps to circumvent operations by alteration of diet or the time of day at which food is given, in order to make things difficult for the suspected person. If medicines are suspected as being tampered with they should be changed, in such a way that a poison may demonstrate itself by taste or colour change , or a dye-stuff may be added so that the addition of an alkaline or acid substance would be seen A nurse may be engaged or a previous nurse changed, and given strict orders to prepare food, but she should not be given a hint of what is going on Visitation of the patient by a suspected person may be forbidden for *ordinary medical* reasons or only allowed in the presence of the nurse The aim of the doctor should be *not* only to protect his patient, but also, if possible, to detect the poisoner, and thus prevent future attempts If serious symptoms develop removal to a nursing home or hospital should be insisted on, so that the patient is out of reach of danger Careful notes of everything that happens must be made at the time and kept for reference Specimens of excreta likely to contain poison should be saved, especially those passed within 21 hours of the time when the poison was suspected of being given The doctor should himself carry them to his house and should keep them in a clean closed vessel, sealed and labelled A brother practitioner should be called in consultation and suspicions communicated to him, in this way an independent witness is made available if required, and, moreover, the benefit of advice for future conduct of the case is obtained Further than this it is impossible to go unless suspicions are supported by fact Without provable facts it is impossible to set the machinery of the law in action. A communication to the police would at once start an elaborate investigation, questioning, and even perhaps detention of individuals possibly a search of the house and probably publicity would ensue, all of which, unless the suspicions were correct, would at least inflict great hardship on innocent individuals At worst it could lead to a possible action for damages against the medical attendant and the ruin of his practice should the suspicions be not subsequently confirmed

When information is given to the doctor by a member of the household suggesting that a third person is attempting to poison the patient, the doctor should advise the informer to communicate with the police if sufficient proof is available Probably the proof will be insufficient and no steps will be taken The doctor should then invite the individual to cooperate with him in endeavouring to bring the allegation to a satisfactory termination, but he must at the same time be on his guard against false evidence actuated from interested motives and against an attempt of a guilty person to throw the blame elsewhere The doctor must feel his way with the utmost caution, but he cannot afford to neglect the information In such a case, if the patient is confined to his bed through illness, the doctor may with advantage urge removal to a nursing home or hospital

In some cases the doctor may first hear of the suggestion of poisoning through the supposed victim (A), who will generally come armed with various articles of consumption believed to be poisoned Such cases may be divided into the following headings (*a*) suspected poisoning of (A) by (B), motive unknown, (*b*) suspected poisoning of (A) by a lunatic or borderline case or uncertifiable case—e g, husband suspected by wife, (*c*) suspected poisoning of (A), a borderline case, by a relative, (*d*) suspected poisoning of (A) by a person interested—for example, financially—or by a companion likely to benefit Regarding these conditions motive will have been found by the informant who believes that the poisoner has a grievance—e g, love affairs, pecuniary reasons, and so forth. Generally speaking, these charges are without foundation, and incipient insanity of either party dependent on changes associated with involutional states must be borne in mind The practitioner's duty here is simple He will at once instruct the victim to collect material or excreta for analysis, or will arrange for the analysis to be made on the material already produced, at the expense of the victim, and advise the victim to wait for the result before action is taken by him or her He will be prudent to get the needful fees for analysis in advance If the victim is in a highly nervous state from worry, the practitioner should suggest his going away to friends until the result is known. When the result is known the victim may be satisfied that he or she is wrong or, what is more likely, will not be satisfied, alleging that the analysis failed to find some subtle poison If the doctor cannot alleviate suspicion by persuasion he can but advise going to the police, but on no account should he take this step himself If he knows of some reliable relative who will intervene, he should urge the patient to inform the relative so that a consultation may be held as to what steps are to be taken Inquiry by the police will, of course, come to nought in that large majority of cases where no crime exists, but may result in satisfaction to the aggrieved party The police will interview the doctor, who should give a full and unbiased opinion of the state of affairs as he sees them. If the doctor can satisfy himself that the aggrieved person is in an abnormal mental state, he may be well-advised to inform the person against whom the allegations have been made with a view to preventing possible assaults or retaliation, and possibly with a view to having the individual certified or provided with a nurse companion.

The Problem after Recovery

The patient's recovery after accidental, suicidal, and self-administered poison does not necessarily end the problem for the family doctor The doctor is often puzzled when a case recovers as to what is his duty regarding the lodging of information Attempted suicide and the taking of poison for the purpose of abortion, for example, are felonies and are punishable by law Technically, the doctor is an accessory after the fact if he fails to disclose what knowledge he is in possession of But in how many cases is his knowledge founded on established fact? Further, what information he may have discovered will be hearsay or the statement of a person unsupported by witnesses, so that when he has to testify he may be met with a denial One person's word against another, unsupported by corroboration, will not be accepted in a court

Further—and this is the consideration that might have been put first—the doctor is bound by his professional obligations to his patient whose faith in these obligations resulted in a confession which would not otherwise have been made The point was dealt with at some length by the late Mr Justice Hawkins, who fully realised the position of the doctor and made a pronouncement which is worth quoting in full —

> "It was also said by the medical witnesses (referring to evidence given in the case) that, if in the course of professional practice they came across a case which indicated either that a crime had been committed or was about to be committed, under these circumstances they were bound to divulge it To whom? To the Public Prosecutor! If a poor, wretched woman committed an offence for the purpose of getting rid of that with which she was pregnant, and of saving her character, her reputation, and, it might be, her very means of livelihood, and if a doctor was called in to assist her—not in procuring abortion, for that in itself was a crime—but called in for the purpose of attending her and giving her medical advice—that she might be cured so as to go forth to her business—he doubted very, very, very much whether he would be justified in going forth and saying to the Public Prosecutor, 'I have been attending a poor young woman who has been trying to procure abortion with the assistance of her sister She is now pretty well, and is getting better, and in the course of a few days she will be out again, but I think I ought to put you on to the woman' To his mind, a thing like that would be monstrous cruelty He did not know what the jury's view would be, he spoke only of his own"

The judge is quoted only in connexion with cases of unsuccessful suicide, and of abortion, where the doctor has appeared in his professional capacity

There is also the case where a person has purchased the poison and handed it to the poisoned person, who voluntarily took same—e g, for procuring abortion In absence of definite evidence of the fact the doctor can do nothing, but in the presence of positive evidence it may be his duty here to give information so that the accomplice may be apprehended, when the taker of the poison would probably become a Crown witness In the case of a death pact between two persons by poison where one recovers, the doctor should inform authority, and the recovered person will probably be charged with felony

The question of informing the convalescent patient of the nature of the illness will depend on the analyst's report If positive, the patient must be informed of the nature of his illness, and if the evidence has been sufficiently strong to detain anyone, this fact must also be communicated to him If, however, no action is likely to be taken against any suspected person, the suspicions had better not be communicated to the patient but further investigation left to his initiative

The Cost of Analysis

In cases of suspected homicidal poisoning, whether the poison is known or not, the medical attendant should reserve specimens of excreta or partly consumed food for analysis. A difficulty arises regarding the cost of the examination. It is hardly likely that the suspected homicide will agree to pay for the analysis, thus providing evidence against himself, and, indeed, it may be unwise to acquaint him of the fact that poisoning is suspected at this stage of the investigation. Any mention of the fact to the patient will also be equally undesirable, unless the patient himself suspects poison. The doctor is, therefore, faced with two alternatives: (1) To bear the cost himself, which is obviously unfair, as his chances of the recovery of the cost is remote, whatever the issue. (2) To inform the police and request them to take the necessary steps for an analysis. This, as has been already pointed out, will necessitate inquiries at a stage when the medical attendant desires to avoid them. There is, however, a third course which may assist the medical attendant in his difficulty. He may make application to the Under Secretary of State, Home Office, for assistance, giving a full account of the matter and the reasons for his suspicions. The Under Secretary of State may then cause an analysis to be made at the expense of public funds, if he thinks that the facts warrant it. The authorities at the Home Office, fully realising the delicacy of the doctor's position, can delay active inquiry into the case until the result of the analysis is known. Such an application should only be made in serious cases, but is a resort which may be of great assistance in an anxious situation. Should the Home Office consider that it is a case for their intervention they will inform the doctor of the necessary procedure.

What to Reserve and How to Reserve It

It is obvious that every article of food or medicine which may be suspected of being tampered with should be reserved and kept under lock and key by the medical attendant. All excreta, urine, faeces, and vomit should be similarly treated, and especially those leaving the body within 24 hours of the time when the suspected poison was believed to have been taken. However, over-anxiety in suspected cases of the doctor may defeat his own object by putting the poisoner on his guard and causing anxiety to the patient. The doctor may have to be content with reserving one or two articles; positive findings in excreta are of greater value, as they prove the fact that the individual did actually imbibe poison. Generally speaking, the urine will be the most valuable specimen to reserve and the easiest to procure, and in order to obtain sufficient the doctor can ask for night and morning specimens and have them passed in his presence. The material or materials reserved should be placed in clean bottles, preferably rinsed out by the doctor just before filling. They should be securely corked and sealed by him and labelled with the patient's name, date of collection, the nature of the material and the initials of the doctor. On no account whatever should any preservative be added. It does not matter if the contents become fouled during the time which elapses between the taking of the specimen and the analysis. The possible risk of a poison becoming decomposed is slight, but the addition of an antiseptic (in most cases a poison) may so complicate the examination that the analyst may be unable to give a definite opinion on the presence of poison. The doctor should content himself with keeping the bottles in a cool place.

Dying Declarations

When a patient is dying but is of sufficiently clear mind to give an account of the facts leading to his illness, it will be the duty of the medical man to take a dying declaration. In cases of death by poison it will probably be rare that an opportunity will occur for a declaration to be made, but in accident and suicide cases they may be of importance in removing suspicion from a third person in the investigation of the cause of death. A dying declaration is an exception to the strict laws of evidence which exist in criminal courts. The essential point of these declarations is that the individual must realise that he is about to die and has no hope of recovery. They should be made in the presence of a magistrate if time permits, but if necessary must be taken down by the medical attendant. The following lines should be observed by the doctor. He should:—

(1) Secure a trustworthy witness.

(2) Make certain that the individual is convinced that he is about to die; a statement by him to that effect should be made in the declaration.

(3) Write the exact words of the patient.

(4) Ask only those questions which are deemed essential to clear up any ambiguities or doubtful points, and ask as few as possible.

(5) Record questions and answers.

(6) [illegible] only of what was said by the dying man or woman.

(7) Read the declaration to him and get him to sign it or put a mark.

(8) Sign it yourself and obtain the signature of the witness.

(9) If unconsciousness supervenes record as much as you can and sign it and obtain signature of the witness.

Should the patient recover, these declarations are invalid, as the individual is then able to give evidence himself and be cross-examined. Dying declarations are based on a legal assumption that a person in sight of death speaks the truth.

Withholding the Certificate

If the medical attendant cannot give a certificate of death from some natural cause the coroner must be informed. If the patient is a stranger to him he should be specially on his guard, since a homicide may send for a stranger rather than a medical man who knows the family well. Or he may send for a strange doctor to witness the body and, failing to obtain a certificate from the latter, he may then apply to the family doctor, who knows the deceased's "constitution" and may be tempted to give a certificate on the strength of that general knowledge.

In all cases of death from poisoning it is the duty of the medical attendant to withhold certification of the fact and immediately to inform the coroner of the circumstances. This should be done as soon as possible, to enable the authorities to commence inquiries at the earliest possible time. Thus the event of accident or suicide will be cleared up without any suspicion, and at the same time the police will be best enabled to collect information to apprehend any guilty party in homicide cases. In cases where poison is only suspected the medical attendant must consider whether his suspicions are sufficiently certain and capable of proof to warrant his withholding the certificate. Further, he must consider whether anyone else is likely to inform the police if he does not; whether the police are likely to hear of the matter through any gossip, and whether any open accusation has been made in the household of the deceased in his, the doctor's, hearing. If scandal has occurred it is the medical attendant's duty to put the facts before the coroner and to abide by his decision.

The doctor should, before leaving the house, take possession of any bottle, tumbler, food, or material suspected of containing poison. Relatives even in suicide cases often attempt to destroy this evidence in the vain hope that any stigma resulting from the coroner's inquest may be avoided. The doctor may be pressed to give a certificate of death to avoid these inquiries, but he must be firm in refusal, else he may find himself in a very difficult position with the coroner, to say nothing of a possible charge of false certification of a legal document.

Chronic Poisoning and Notification

In the case of patients suffering from chronic poisoning caused through the nature of their employment, it is the duty of the medical attendant to notify the Chief Inspector of Factories at the Home Office, giving the name and address of the patient and the nature of the disease from which the patient is the

the time when the poison was suspected of being given The doctor should himself carry them to his house and should keep them in a clean closed vessel, sealed and labelled A brother practitioner should be called in consultation and suspicions communicated to him, in this way an independent witness is made available if required, and, moreover, the benefit of advice for future conduct of the case is obtained Further than this it is impossible to go unless suspicions are supported by fact Without provable facts it is impossible to set the machinery of the law in action A communication to the police would at once start an elaborate investigation, questioning, and even perhaps detention of individuals, possibly a search of the house and probably publicity would ensue, all of which, unless the suspicions were correct, would at least inflict great hardship on innocent individuals At worst it could lead to a possible action for damages against the medical attendant and the ruin of his practice should the suspicions be not subsequently confirmed

When information is given to the doctor by a member of the household suggesting that a third person is attempting to poison the patient, the doctor should advise the informer to communicate with the police if sufficient proof is available Probably the proof will be insufficient and no steps will be taken The doctor should then invite the individual to cooperate with him in endeavouring to bring the allegation to a satisfactory termination, but he must at the same time be on his guard against false evidence actuated from interested motives and against an attempt of a guilty person to throw the blame elsewhere The doctor must feel his way with the utmost caution, but he cannot afford to neglect the information In such a case, if the patient is confined to his bed through illness, the doctor may with advantage urge removal to a nursing home or hospital

In some cases the doctor may first hear of the suggestion of poisoning through the supposed victim (A), who will generally come armed with various articles of consumption believed to be poisoned Such cases may be divided into the following headings (*a*) suspected poisoning of (A) by (B), motive unknown, (*b*) suspected poisoning of (A) by a lunatic or borderline case or uncertifiable case—e g , husband suspected by wife, (*c*) suspected poisoning of (A), a borderline case, by a relative, (*d*) suspected poisoning of (A) by a person interested—for example, financially—or by a companion likely to benefit Regarding these conditions motive will have been found by the informant who believes that the poisoner has a grievance—e g , love affairs, pecuniary reasons, and so forth. Generally speaking, these charges are without foundation, and incipient insanity of either party dependent on changes associated with involutional states must be borne in mind The practitioner's duty here is simple He will at once instruct the victim to collect material or excreta for analysis, or will arrange for the analysis to be made on the material already produced, at the expense of the victim, and advise the victim to wait for the result before action is taken by him or her He will be prudent to get the needful fees for analysis in advance If the victim is in a highly nervous state from worry, the practitioner should suggest his going away to friends until the result is known. When the result is known the victim may be satisfied that he or she is wrong or, what is more likely, will not be satisfied, alleging that the analysis failed to find some subtle poison If the doctor cannot alleviate suspicion by persuasion he can but advise going to the police, but on no account should he take this step himself If he knows of some reliable relative who will intervene, he should urge the patient to inform the relative so that a consultation may be held as to what steps are to be taken Inquiry by the police will, of course, come to nought in that large majority of cases where no crime exists, but may result in satisfaction to the aggrieved party The police will interview the doctor, who should give a full and unbiased opinion of the state of affairs as he sees them. If the doctor can satisfy himself that the aggrieved person is in an abnormal mental state, he may be well-advised to inform the person against whom the allegations have been made with a view to preventing possible assaults or retaliation, and possibly with a view to having the individual certified or provided with a nurse companion

The Problem after Recovery

The patient's recovery after accidental, suicidal, and self-administered poison does not necessarily end the problem for the family doctor. The doctor is often puzzled when a case recovers as to what is his duty regarding the lodging of information Attempted suicide and the taking of poison for the purpose of abortion, for example, are felonies and are punishable by law Technically, the doctor is an accessory after the fact if he fails to disclose what knowledge he is in possession of But in how many cases is his knowledge founded on established fact? Further, what information he may have discovered will be hearsay or the statement of a person unsupported by witnesses, so that when he has to testify he may be met with a denial One person's word against another, unsupported by corroboration, will not be accepted in a court

Further—and this is the consideration that might have been put first—the doctor is bound by his professional obligations to his patient whose faith in these obligations resulted in a confession which would not otherwise have been made The point was dealt with at some length by the late Mr Justice Hawkins, who fully realised the position of the doctor and made a pronouncement which is worth quoting in full —

> "It was also said by the medical witnesses (referring to evidence given in the case) that, if in the course of professional practice they came across a case which indicated either that a crime had been committed or was about to be committed, under these circumstances they were bound to divulge it To whom? To the Public Prosecutor! If a poor, wretched woman committed an offence for the purpose of getting rid of that with which she was pregnant, and of saving her character, her reputation, and, it might be, her very means of livelihood, and if a doctor was called in to assist her—not in procuring abortion, for that in itself was a crime—but called in for the purpose of attending her and giving her medical advice—that she might be cured so as to go forth to her business—he doubted very, very, very much whether he would be justified in going forth and saying to the Public Prosecutor, 'I have been attending a poor young woman who has been trying to procure abortion with the assistance of her sister She is now pretty well, and is getting better, and in the course of a few days she will be out again, but I think I ought to put you on to the woman' To his mind, a thing like that would be monstrous cruelty He did not know what the jury's view would be, he spoke only of his own"

The judge is quoted only in connexion with cases of unsuccessful suicide, and of abortion, where the doctor has appeared in his professional capacity

There is also the case where a person has purchased the poison and handed it to the poisoned person, who voluntarily took same—e g , for procuring abortion In absence of definite evidence of the fact the doctor can do nothing, but in the presence of positive evidence it may be his duty here to give information so that the accomplice may be apprehended, when the taker of the poison would probably become a Crown witness In the case of a death pact between two persons by poison where one recovers, the doctor should inform authority, and the recovered person will probably be charged with felony

The question of informing the convalescent patient of the nature of the illness will depend on the analyst's report If positive, the patient must be informed of the nature of his illness, and if the evidence has been sufficiently strong to detain anyone, this fact must also be communicated to him If, however, no action is likely to be taken against any suspected person, the suspicions had better not be communicated to the patient but further investigation left to his initiative

THE LANCET.

NDON: SATURDAY, JANUARY 1, 1927.

OSPITAL ISOLATION OF MEASLES.

new policy[1] in respect to the isolation of s which has recently been decided upon by etropolitan Asylums Board, should help to rate conditions which press hardly on child life poorer classes of the metropolis. The scheme, be remembered, consists in allocating to the ent of measles, at times when the disease is nt, a large proportion of the beds in the public hospitals hitherto assigned to scarlet fever, ality of which, in hospital-treated cases, is oout one-tenth of that of measles. Were the r of beds in these hospitals unlimited, the on of both diseases up to the full requirements present no difficulties. There would be room and no application for removal in the case of disease would have to be rejected. Unfor- y, during times of high measles prevalence riod of which usually extends over three or onths and recurs about every second year, al number of beds available in the fever ls is not commensurate with the requirements of alone and cases can only be received at the of scarlet fever. This in effect involves the n of cases for admission in respect to both if the beds are to be utilised to the best ge, and opinions may differ as to the grounds h a case should be regarded as qualifying for on—whether, for instance, the severity of the or the adverse home conditions should be the ning factor It is, however, admitted that ung complications are prone to supervene in occurring in a poor home, although the may have bid fair to pursue a favourable t the outset. Then there is the question who ost suitable person to make the selection— cal attendant or the health visitor acting as of the medical officer of health. Ultimately it where the available accommodation is he decision must rest with the latter official r whether he obtains his information about from the general practitioner or through his own subordinates. The chief aim is e of delay in procuring admission to hospital ystem best adapted to secure this is the best tion.

idon, equipped as it is with a number of lation hospitals, each containing some 400 eds, it should practically always be possible te to measles a number of separate wards, admission of this disease is not attended same difficulties as in provincial towns with tion of, say, 30 000 to 150,000, where the pital accommodation is usually limited to ds. The difficulties attending any attempt for measles in these circumstances is fully d by many of the provincial health officers. ld gladly follow the example of London. Within their limited accommodation these municipal hospitals are designed to receive not only scarlet fever and diphtheria, but on occasion cases of typhoid, cerebro-spinal fever, or encephalitis as well; at the best of times there remain a few cases of scarlet fever and diphtheria under treatment, and a spare ward is rarely available Consequently, surplus accommodation in the smaller fever hospitals cannot be expressed in terms of spare wards, but as spare beds in occupied wards, which cannot be used for measles. It is true that at Fazakerley, for instance, measles is treated with all other infections in the same ward by the method known as " bed isolation, but for this purpose two safeguards are essential to success—viz., a tried and specially trained nursing staff and a certain measure of selection of cases. And these conditions would be difficult to secure in the smaller hospitals with their fewer beds and frequently changing staff. When however, it is possible to spare a small ward for the purpose, it is of paramount importance that removal to hospital should be effected at the earliest possible moment, in order to forestall, if possible, the supervention of capillary bronchitis and broncho-pneumonia In the selection of cases for removal both factors—severity of attack and unsuitability of the home environment—should be taken into account if the best results are to be secured. The advent of broncho pneumonia is, indeed, a very serious handicap and early removal to hospital is a potent influence in its prevention, but even should this dread complication have already supervened, manifest improvement in the child s general condition often follows admission to a hospital ward, where it meets, perhaps for the first time, with a plentiful supply of fresh air, good food and proper nursing

Admittedly difficulties are encountered in catering for measles in the smaller isolation hospitals, indeed they are frequently regarded as insurmountable by the boards which administer the hospitals for infectious diseases Some of these, as a contemporary trenchantly points out[2] have " degenerated into penitentiaries where convalescent scarlet fever is prevented from obtaining efficient treatment." In rural areas, at all events, the local board is too apt to take the view that the removal of an infectious patient from the community is the whole object of hospital isolation Victims of infectious diseases are hurried off to the fever hospital whose staff and equipment fall far short of requirements. Irregularity of demand and the need for economy are mainly responsible for this; it is costly and difficult to secure a rapid increase in the number of experienced nurses in response to a sudden and unexpected call. But the aim of any progressive isolation hospital board should be to give precedence to infections which are serious and need specialised treatment, and to discard segregation as a primary function Even if only a limited number of serious cases of measles can be received into hospital from among the inhabitants of the poorer districts it is well worth doing It cannot be too strongly insisted that the saving of life is the main consideration, and the medical officer responsible for the allocation of beds in the local hospital in striving to achieve this end should be free to pursue the course which in his opinion is most likely to prove successful. Where the control of the local isolation hospital is vested in the medical officer of health for the district the limited number of beds at his disposal is likely to be utilised to the best advantage, but where, as is often the case in country opinion of his doctor is suffering. Notice must also be sent to the Factory Inspector and to the certifying surgeon of the district in which the factory or workshop is situate.

---

[1] LANCET, Oct. 23rd p 865, and Nov. 6th, p 974

[2] Medical Officer Dec. 4th, 1926, p 237.

The diseases to which this applies are lead, phosphorus, arsenical and mercurial poisoning, and to infections from anthrax. A fee of 2*s* 6*d* is paid for the notification.

Sale of Poisons.

The statutes governing the sale of poisons are numerous and the provisions varied. Medical men, especially those who dispense for themselves, should acquire a working knowledge, in particular of the Poisons and Pharmacy Acts, 1868–1908; the Medical Act, 1858; the Medical Council Act, 1862; Dangerous Drugs Acts, 1920, 1923; Narcotic Drugs Orders, 1916, 1918. These various Acts lay down conditions under which various poisons and dangerous and narcotic drugs may be prescribed and dispensed, the keeping of records; schedules of poisons within the meaning of the Acts and conditions under which they may be sold by a doctor, by chemists, and by shopkeepers; the delegation of dispensing duties to unqualified persons and sale of poisons to unknown persons; regulations for labelling and placing of poison in distinctive bottles recognisable in the dark, &c; sale of narcotic drugs to lay people and officers of the armed forces of the Crown; colouring of arsenic before sale of that which is not used for medicinal purposes. In minor details the position varies in Ireland compared with the rest of the British Isles. In addition there are two Acts which may be mentioned as having a possible bearing on poisoning; these are (1) Poisoned Flesh Prohibition Act, 1864; (2) Drugging of Animals Act, 1876. These Acts are designed to prevent the unauthorised destruction of animals other than the destruction of vermin, but prosecution may be undertaken in the event of poisoned food being left about in such a manner that it might be consumed by human beings.

Range of Poisons Obtainable

The Schedules of the Poisons and Pharmacy Acts, Arsenic Act, and the Dangerous Drugs Act limit the range of poisons likely to be used in this country and have a further bearing on the chance that any Act may be selected. The profession or trade of an individual must, however, be borne in mind, since he may have special access to poisons. Also, though to a less extent, failure to carry out the provisions of the Acts must be allowed for. Chemical manufacturers, chemists, and laboratory workers are able to obtain an almost unlimited range of poison, and can further obtain these poisons in a pure state without the addition of colouring matter.

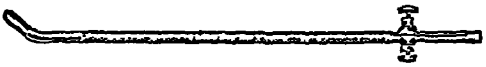
There can be no doubt that the limitation of the sale of poisons in this country, and the recording of sales in the poison book at the place of purchase, has greatly limited poisoning not only in amount but also in range. Since the operation of the Dangerous Drugs Act the falling off of suicide from narcotic drugs is marked. When coal-gas, phosphorus (vermin-killer), arsenic (weed-killer or sheep-dip), strychnine (vermin-killer), barium (vermin-killer), antimony, mercury, and oxalate have been excluded, there are but few poisons which are likely to be obtained for homicidal purposes. The strong acids, alkalies, cyanides, carbolic group and, indeed, some of those mentioned above are unlikely to be used owing to the impossibility of disguise of taste and appearance. The possibility of scheduled and rare poisons being used must not be entirely disregarded, since these may be obtained by individuals abroad, but the chances of such access are generally ascertainable.

Accidental cases frequently arise from mistakes in handling of dispensed medicines, fatal medicines and lotions, and disinfectant solutions. Attempts to limit these have been made by regulations for keeping, dispensing, and selling of poisons carried by the Pharmaceutical Society with consent of the Privy Council, and these have done much to prevent accidental poisoning.

New Inventions.

PROSTATIC DIATHERMY.

In order to apply heat to the prostate by a diathermy current I have used the electrode illustrated herewith. It is made in the shape of an ordinary cystoscope, the beak being made of vulcanite and the horizontal part of metal. One inch from the junction of the vulcanite and metal the metal is decreased in diameter so as to allow the greater part of the shaft to be covered by an insulating layer of silk web. The electrode is hollow, and a thermometer is fitted to it so that the temperature of the exposed metal part can be kept under constant observation. The electrode is used in combination with a lead girdle electrode round the pelvis below the iliac crest, in the same way as Cumberbatch has described for use in diathermy of the cervix. The internal electrode is passed into the bladder and the end is then depressed until the metal is horizontal; it is then withdrawn until the beak impinges on the internal meatus. Measurements in many cases have shown that the internal electrode in this position is very nearly in the centre of the lead girdle (within ¼ inch). With the diathermy apparatus which has been used with it, a current of about 700 m.a. records a temperature of 114° F., which had been found not to cause any pain and not to be followed by any unpleasant after-effects. It is too early yet to report on the clinical value of this method of treatment, but it is here described as a method of applying heat by diathermy to the prostate.

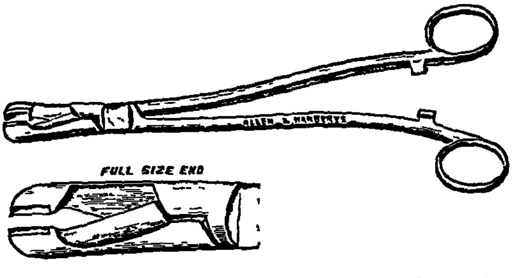


This electrode has been made for me by the Holborn Surgical Instrument Co.

G. F. Stebbing, M.B., B.S. Lond.

COMBINED SCISSORS NEEDLE-HOLDER FOR PERINEORRHAPHY.

The instrument here illustrated is most useful in the repair of perineums. No operation on the female genital organs causes so much irritation to the operator, requires so much assistance, or repays the patient and the community more than a successful operation for prolapse. The swabbing of the wound, the retraction of the cut edges of the vagina, the insertion, tying, and cutting of the numerous sutures, requires many hands. I find the equivalent of one hand is saved by this instrument. The idea was suggested by seeing Mr. H. D. Gillies use his scissors needle-holder. The instrument explains itself. The assistant swabs and retracts by holding the short end of the last suture. The operator, by means of the instrument, inserts his suture, ties the suture with the instrument still in his hand, and then cuts the last short end and the long end of his present suture with the scissors in the needle-holder.



The scissors needle-holder is manufactured by Messrs. Allen and Hanburys, Ltd., of Wigmore-street, London, W. 1.

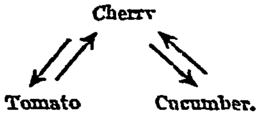
ageing, for the expressed juice retains its infectivity for a very long time—as long as three years Now the virus of the disease in the cucumber behaves quite differently The infectivity of the expressed juice disappears rapidly in one or two days, it is destroyed by drying, by treatment with alcohol and by heating. But the infective agents of both the tomato and the cucumber will pass through a Berkefeld filter and will remain active in dilutions of 1 1000 These observations would appear to furnish strong evidence in support of the theory of the dissimilarity of the two diseases Against this must, however, be set the observation that the disease has been transmitted from the cucumber to the tobacco plant The disease has not so far been transmitted directly from the tobacco plant to the cucumber, but only indirectly by first infecting the pepper from the tobacco and then transmitting it to the cucumber The virus of the disease in the tomato behaves towards the various agents mentioned above in the same way as the virus from the tobacco plant—that is to say, it is resistant to ageing, drying, heating and to treatment with alcohol. Here again the disease cannot be transmitted from the tomato naturally affected with the disease to the cucumber, or vice versa, but it can be transmitted from the ground cherry naturally affected with the disease to the cucumber and vice versa. The ground cherry (physalis) can also be infected with the disease from the tomato and from the cherry thus infected from the tomato the disease can then be transmitted to the cucumber. The ground cherry can therefore serve as intermediate host of the virus between tomato and cucumber. This relationship can be expressed in the following diagram :—



Up to this point mosaic disease presents an apparently inextricable maze of contradictions In a recent paper [1] presented for the degree of Ph D at the University of Wisconsin Mr M N. WALKER has attacked the problem and has succeeded in finding a way out. He has studied the resistance of the virus to the various agencies mentioned above in the tomato the ground cherry and the cucumber when naturally affected with the disease He then produced the disease in those three plants by cross inoculation (in the tomato from the ground cherry, in the ground cherry from the tomato, in the ground cherry from the cucumber, in the cucumber from the ground cherry, and in the cucumber from the tomato, using the ground cherry as intermediate host), and studied the behaviour of the virus in these experimentally transmitted diseases He found that the virus of the disease in the ground cherry was always resistant to ageing, heating drying, and alcohol, whether the disease had affected the plant spontaneously or whether it had been transmitted to it from the tomato or the cucumber. The same held good for the virus of the disease in the tomato In the disease of the cucumber the virus was always found to be readily destroyed by these agencies whether the disease had affected the plant spontaneously or whether it had been transmitted to it from the ground cherry or indirectly from the tomato The evidence is therefore in favour of a single cause or agent for all mosaic diseases but the evidence also indicates that the properties of this causal agent may be decidedly changed according to the species of plant which it has infected Although the author does not say so the interest of the work on mosaic disease extends beyond the solution of a particularly intricate problem The phenomena observed in this case will have to be taken into consideration in the investigation of virus diseases in animals. Differences in the susceptibility to such agencies as ageing, drying heating alcohol would be considered as reliable evidence for the differentiation of bacteria or of chemical substances, which cannot be isolated, such as ferments, immune bodies and so on But such evidence can no longer be accepted as conclusive for a virus This peculiarity may possibly be due in part at any rate, to the loose use of the term "virus" In mosaic disease infection is brought about experimentally by the expressed juice of the plant and to this the term virus is applied. But this extract is merely the vehicle for the infecting agent and contains in addition a great many other substances, the presence of which may affect the resistance of the virus to the various agencies mentioned above and even its infecting power for a different species of plant, to such an extent as to give to the virus the appearance of a specific pathogenic agent which it does not really possess

Now, the same considerations hold good for virus diseases in animals Here, also the transmission of the infection by tissue extracts or exudates has always been attributed to the presence of a virus by itself, and the presence of other substances which might affect the biological behaviour of the virus has been disregarded As a result, the same problems have arisen as in mosaic disease of plants Recent work on foot-and-mouth disease has yielded evidence which is interpreted by some as indicating a plurality of viruses, all of which produce the disease in different species According to the report of the American Commission, the horse is very resistant to the experimental infection with the virus from foot-and-mouth disease of other species But it suffers spontaneously from a disease called vesicular stomatitis, which resembles foot-and-mouth disease. Infective material from a vesicle of this disease when injected into guinea-pigs produces typical foot-and-mouth disease The diseases due to the vaccinia virus present a similar picture A great many different species of the higher animals are susceptible to the disease. But if the disease occurs spontaneously in one species its infectivity is very often narrowly restricted to that particular species Thus sheep-pox is spontaneously only infective for sheep and not for goats or other species of animals If the disease occurs in goats its spontaneous infectivity is restricted to goats, and does not extend to sheep. But experimental transmission can often break through this specificity. In some cases what appears to be a distinct disease has been shown to be due to the vaccinia virus Thus the infectious disease of horses known as pustulous stomatitis, which breeds true in that species, is produced by a virus indistinguishable from that of vaccinia so that the disease is, in fact, a different type of the horse-pox of Jenner. Again, the virus of epithelioma contagiosum of fowls is, according to some observers, identical with that of vaccinia, although this identity is denied by others The similarity of these conditions to those obtaining in mosaic disease of plants is obvious On the one hand there is the wide distribution through different species On the other there are the same problems of the curious limitations of infectivity, and they have probably arisen for the same reason that while by a loose process of reasoning the virus is identified with the infective material, the latter contains other substances which modify the action of the virus. This is very clearly exemplified by the recent work in another group of virus diseases—namely, the filterable malignant neoplasms of the fowl, discovered by Rous He described three different types of tumours and a few others have been recorded since by other workers Each type of tumour yields an extract which will transmit the disease in the same breed of fowls and reproduce exactly the same type of tumour. The pathogenic action of these tumour extracts is, therefore, highly specific and as the extract was identified loosely with the virus, the specific pathogenic action was attributed to the virus. It thus became necessary to assume a different virus for each type of tumour. But since these filterable malignant neoplasms do not spread by infection, but, like the non-filterable districts, the control is in the hands of a joint hospital board, the health officer is not infrequently faced with opposition, if not actual obstruction In circumstances such as these the only course open to him is to make urgent and repeated representation to the controlling authority as to the way in which, in his opinion, existing beds should be allocated, at the same time calling the attention of the board to the responsibility which they must be prepared to shoulder in the event of refusal Tactful persistence may in the end bear fruit even to the extent of securing extension of existing accommodation

IMITATION AS A FACTOR IN SUICIDE

A DISCUSSION on carbon monoxide poisoning, which took place at a recent meeting[1] of the Medico-Legal Society, was concerned with the increase of suicide in this and other countries, and particularly with the frequent use of coal-gas for that purpose Such a use was almost unknown in this country before 1895, but it now accounts for one-third of the suicides in some Scottish towns, whilst in England the number of suicides by this means has more than trebled in the last six years Although the addition of water-gas to the domestic supply adds to its toxicity and, according to Dr DOUGLAS KERR, has been followed by an increase of accidental poisonings, yet the increase of suicide by inhaling coal-gas is an independent phenomenon doubtlessly affected by the publication of detailed reports of the methods used in particular cases These reports appropriate enough in a text-book of forensic medicine, have taught the public that in coal gas is to be found a means of escape from life's troubles that closely fulfils the classical three requirements of successful therapy—*cito, tute et iucunde* But even when the influence of this knowledge is admitted we cannot be sure that it affects more than the manner of the suicide, for it may be argued that if the one method were not available some other would be used This is true to some extent, for with the increase of suicides by poison, including coal-gas, there has been a diminution of those in which clumsier means of voluntarily ending life were employed, if it were a general truth it would stultify any precautions by which we seek to impede the obtaining of poisons lest they should be used for suicidal purposes Yet, though we can only speculate how far opportunity is responsible for suicide and how far we can expect to influence its incidence by precautionary measures, there can be no hesitation in condemning the publication of descriptions of easily achieving the end There are sources of poison accessible to practically everyone—in gardens and hedgerows, for example—and a sensational case of the use of some vegetable poison, reported with full details, might start a new fashion by providing opportunities that are now lacking through ignorance It may be fortunate that the story of the death of Socrates has no news value

To find ourselves advocating that knowledge of easy means of self-destruction should be withheld from the public is, however, a situation that itself invites comment Imitation and suggestion may be offered in partial explanation of the increase of suicide, but they can only operate in the presence of other determinants These determinants, so far as they are unknown, constitute the actual problem, and their investigation is imperfect, for obvious reasons Friends and relatives often testify at an inquest that the deceased had no known reason for his act, and the frequent invocation of "nervous breakdown" hides under an evasive nomenclature our ignorance of causes The stereotyped verdict of 'Suicide whilst temporarily insane" is, of course, a relic of the times when a verdict of *felo de se* involved both denial of religious burial and interference with the rights of successors

It is probable that relatively few suicides occur among sufferers from the major psychoses, some must be attributed to misfortune or physical illness, which has led to a reasoned decision on the part of the victim, alcoholism, which itself calls for psychological explanation, accounts for others, but, to judge roughly from newspaper reports, a great many occur when the victim has been in a state of emotional disturbance out of proportion to any ascertainable cause The last group probably accounts for the increasing rate, and since such emotional disturbances are commonly found among the sufferers from the varied psychoneuroses, we may expect to have light thrown upon the increase by turning to the study of such patients They commonly tell of compulsive thoughts of suicide (but only, as a rule, to those in whom they have confidence), and it is recognised among those accustomed to handling them that a frank discussion of the thoughts is the best means of avoiding their fulfilment The patient who is without opportunity for this discussion, or avoids it, is in danger of being attracted by any easy means that is offered, he is, we may suppose, the kind of man that is influenced by imitation or suggestion Whether there is an increase in the incidence of psychoneuroses is another question The belief is often expressed that such an increase is taking place, but the belief has been current for at least 40 years and may be only a variant of the everlasting lament for bygone days, it is incapable of verification Modern conditions may, perhaps, offer occasions for manifestations that would otherwise remain latent, and, as a specific instance, the widespread knowledge of the lethal uses of coal gas may provide opportunities for a particular tendency which might, in the absence of the knowledge, never come to fulfilment

THE MECHANISM OF VIRUS INFECTIONS

MOSAIC disease of the tobacco plant has been of interest to animal pathology because it led to the discovery of the class of infecting agents which are microscopically invisible and able to pass through Berkefeld filters It was discovered in 1892 by D IWANOWSKI and called a "contagium vivum fluidum" by M W. BEIJERINCK, who studied the phenomenon in 1899 It is therefore the first representative of a group of infecting agents now known as "the filterable viruses" As happens so frequently in pathological research, further work on mosaic disease, which was carried out mainly in America, complicated rather than simplified the problem One line of investigation showed that mosaic disease could be transmitted to plants of widely separated families, while another line gave indications that the same plant may exhibit several different types of the disease In the genus Solanum, for instance, seven different types of the disease have been described One line of evidence, therefore, leads to the theory of a single mosaic disease spread widely throughout the vegetable kingdom, the other indicates the existence of a number of distinct types of mosaic disease which may occur even in the same species Observations on the resistance of the virus of mosaic disease of the tobacco plant show that it is very resistant to drying and heating and to treatment with alcohol up to a strength of 50 per cent It is also very resistant to emulsions of these brains, instead of neutralising, actually had an activating effect on the virus, and reduced the time of incubation. The activating factor was compared to an aggressin. The period of incubation was also shortened if one or two intradermal inoculations of the glycerinated brain emulsion were given on the days immediately preceding that on which the intracerebral injection of virus was carried out. Perdrau, therefore, came to the conclusion that the failure to transmit encephalitis by a single intracerebral inoculation of human material was due to the presence of an inhibitory substance or antibody in the human cerebral tissue. A technique was devised which consisted of keeping the human brain material in 50 per cent. glycerine saline in the cold, and testing it on the rabbit at weekly intervals for four or five weeks. The rabbits were given intradermal, intracerebral, intradermal and intracerebral inoculations respectively on four successive days. It was found that as the brain material was kept it became more active, and three strains of virus, from as many fatal cases of encephalitis, were isolated. One of these strains proved, by cross-immunity and other tests, to be identical with herpes virus. The other two strains were less virulent and are regarded as similar, though this has not definitely been shown. On the basis of these results, Perdrau upholds Levaditi's view that the virus of epidemic encephalitis is identical with that of herpes febrilis. Owing to the small number of experiments, no definite conclusion can be reached, and confirmation from a much larger series of cases is necessary before Levaditi's contention can be regarded as proved. It is curious that the inhibitory substance or antibody should be present only in human brain material, because the brain of a rabbit dead of the disease is infective in extremely small amounts; doses as small as 0.001 c.cm. of a paper filtrate of a 20 per cent. brain emulsion, when inoculated intracerebrally, will usually prove fatal. Similarly, transmission by corneal scarification can easily be accomplished with an infinitesimal amount of herpes material.

ULTRA-VIOLET RAYS AND VACCINE THERAPY

The discovery of vitamin D, the proof of the antirachitic value of ultra-violet rays from any source, and the experimental photosynthesis of the antirachitic factor in cholesterol or closely associated substances, have set many theorists explaining the probable mechanism of the body's reaction to ultra-violet rays. Dr Paolo Iacchia, writing in *The Pediatria-Archivio*, essays to explain the mass of established facts of actinotherapy, and seeks a rational basis for a special line of treatment that has given hopeful results in his hands. Dr Iacchia believes that the effect of ultra-violet rays is to be explained in an increased ionisation of the electrolytes dissolved in, or loosely combined with, the blood plasma. He counters the criticism that very little ultra-violet light penetrates the skin by pointing out that microtome sections of skin are not comparable with the living skin and that the thickness and cornification of the skin varies in different sites and every individual. He attributes the quicker reaction of children to the ultra-violet rays to the relative thinness and softness of their skin allowing a greater intensity of the incident radiation to reach the cutis vera. The liberation of Ca and P-ions in the plasma would, according to Dr Iacchia, explain the beneficial effects of the rays in rickets, and would be in keeping with the work of Bonino, who finds that these elements are more easily dissociated in human than in cows' milk. Such theorising does not carry us very far, and the interest of the paper to medical men lies in a description of a method of treatment termed by the author "auto-batterio-proteino-terapia," which consists in the subcutaneous injection of pus, or other infective material, rendered sterile by irradiation with a mercury-vapour lamp. In addition to pus from wounds, carbuncles, and the like Dr Iacchia has used sputum from cases of tuberculosis, pneumonia, &c., and infected urine from cases of pyelitis and cystitis. Ordinary pus is emulsified with distilled water, exposed to ultra-violet rays for an adequate time and then injected; sputum is dried on a glass slide as a thin film, irradiated, scraped off, and emulsified as for pus; urine is centrifuged and the débris washed several times to free it from soluble salts before injection. No control of the number of organisms is considered necessary, and, apparently, no severe reactions have followed this form of treatment in Dr Iacchia's hands. He publishes many illustrative cases and declares that, after 20 years of general practice, he is satisfied that this treatment is far better than any recognised form of vaccine or foreign protein-therapy. The results claimed may encourage further work on autogenous vaccines sterilised by ultra-violet rays.

THE SYNTHALIN TREATMENT OF DIABETES MELLITUS

As a result of their work on the chemistry of guanidin, E. Frank and Heyn prepared a series of alkyl derivatives with a long CH_2 chain, and later, in conjunction with M. Nothmann and Wagner, found that the derivative known as synthalin has an action similar to that of insulin when given to rabbits and dogs with pancreatic diabetes. Some account of the results of treating human diabetics with this derivative has already appeared in The Lancet,[1] and further details have now been published in the *Deutsche Medizinische Wochenschrift* for Dec. 3rd and 10th. Frank and Heyn found that synthalin is 100 times as effective as guanidin and that the administration of 3 mg. per kg. body-weight causes in a fasting rabbit hypoglycæmic symptoms which are immediately relieved by glucose. In synthalin the toxic effects which guanidin produces have been so far diminished that no hyperexcitability of the nervous system is noted, and when the drug is administered to man it is necessary to guard against the tendency to vomiting, lethargy, and anorexia which is a feature of guanidin poisoning in cats. It was found that a dose of 4 mg. per kg. of body-weight was fatal to dogs of 6 kg. within three or four days, but if the same dose was spread over a period of two days and then given again after an interval of one or two days the drug was well tolerated. In describing the results of treating human subjects Frank and Heyn point out that although formerly synthalin was given one hour before meals, it was afterwards found better to administer the dose in fluid at the beginning of a meal. It is taken by mouth and the usual single dose is from 20 to 25 mg., the largest quantity which they gave being 125 to 150 mg. over a period of four days. They tried to reduce a sugar excretion of 40 to 50 g. to a few grammes, and started with doses of 20 mg., increasing to 25 mg. when necessary; but they found that when a certain total has been reached a pause of 24 to 36 hours is necessary, as synthalin, though acting more slowly than insulin, has a greater cumulative effect and may cause gastric symptoms. If, however, the urine-sugar tends to rise during the 36-hour interval, an injection of insulin may be given or bread may be omitted from the morning and evening meals. Cases in which the disease is slight may be controlled by small doses at longer intervals. It is possible to transfer patients on insulin to synthalin treatment suddenly if the normal sugar excretion is known, but in severe cases it is advisable to make the change gradually. Excessive doses of the drug cause loss of appetite, epigastric oppression, vague pains and at times diarrhœa, and in the worst cases malaise, nausea, and vomiting. In the course of seven months Frank and Heyn have noticed no cumulative or slowly developing harmful effects, but they point out that there are cases where the treatment cannot be used, and they found that 2 or 3 per cent. of their own patients came into this category. The maximal effect may not be seen for a short time, during which there may be a gradually increasing malignant neoplasms, arise *de novo* and exhibit a considerable variation in type, it is difficult to form a rational conception of their ætiology on the basis of a multiplicity of viruses The conception of GYE is that the same virus is responsible for all the different types, but that the infective action of the virus is rendered specific for a certain type of cell by the presence in the extract of a substance produced by the tumour cells—the "specific factor" On this view the pathogenic action of the virus is determined by the presence in the extract of a substance varying with the tissue which has been infected

---

[1] The Lancet, 1926, ii., 1288.

It has been questioned whether the filterable fowl tumours are due to a living virus, and various speculative alternative explanations have been suggested It is, of course true that an ultramicroscopic virus has not the same concrete reality as a bacterium which can be seen An ultramicroscopic virus is at present essentially a mental conception But, as W E GYE has pointed out in his recent Lloyd Roberts Memorial Lecture [2] the experimental evidence which has led to the formation of such a conception is exactly the same whether we are dealing with the filterable fowl tumours or foot-and-mouth disease, or, indeed, any other so-called virus disease If we question the existence of a virus in one disease, we might equally well question it in all the others The recent work on the various virus diseases, especially the brilliant work of LEVADITI and his collaborators, seems to indicate that the difference between virus diseases and bacterial diseases may be of a more fundamental nature than a mere difference in size of the infecting agent, and that the mechanism of virus infection may be different from that with which our study of bacterial infection has made us familiar Instead of segregating the filterable neoplasms of the fowl from all virus diseases it would seem more reasonable to apply the conception of the mechanism of virus infection, as advanced by GYE for the fowl tumours, to other virus diseases

◆

A DIPHTHERIA FILM

A STRIKING development in public health work is the decision by some life and sickness insurance companies, mainly American, that it is justifiable to use part of their funds in measures designed to improve public health One British company, at least, is now in the habit of making a substantial donation each year out of its available surplus towards some promising line of medical research Another company is paying attention to the possibilities of the cinematograph for public health propaganda, to which a lead has been given by Dr D M Connan's well-known work in Bermondsey, and by the inclusion in the "Bibliography of Industrial Hygiene," issued at Geneva, of a list of cinema films dealing with the health of the community A week or two ago a film entitled "Risk of Diphtheria banished" was shown by the Mutual Property Insurance Company at a gathering in London attended by medical officers of health and others The film displays the record of a Boston family During a violent wave of diphtheria three unprotected children suffered severe attacks, while one immunised sister remained completely well, though virulent diphtheria bacilli were found in her throat Dr Bela Schick is seen inoculating children, and the details of testing and immunisation are shown The film on the whole was successful, though a boy with severe laryngeal paralysis would not often in English practice be allowed in the semi-upright position Little objection could be taken to the general tone of the text, in which grave exaggeration is avoided No suggestion is made at any stage of forcing compulsory immunisation on the public The film, the whole cost of which was borne by the insurance companies concerned, will be loaned free of cost to medical officers of health and responsible health authorities for public exhibition

Annotations.

"Ne quid nimis"

THE PATHOLOGY OF EPIDEMIC ENCEPHALITIS

IN spite of the vast amount of research done since 1919, when C von Economo first described epidemic encephalitis, the problem of its causation has not yet been solved The histopathology has been thoroughly studied by numerous observers, and the anatomical changes in the central nervous system have been fully described and recorded, but the causative agent has so far escaped identification, although new facts concerning its biology are noted from time to time The distressing mental manifestations of chronic epidemic encephalitis have been regarded as post-encephalitic—that is, as the result of tissue damage caused previously by the infection, and not as the result of slow but active multiplication of the virus itself W Freeman,[1] who studied an epidemic in Washington, D C, brings forward evidence to show that the causative agent persists long after the acute symptoms subside, and that the later manifestations of the disease are due to a true acute or chronic infective encephalitis He quotes as a parallel the persistence of the spirochæte of syphilis in the central nervous system for many years before it reveals its presence by the onset of general paralysis or tabes In the report on The Sheffield Outbreak of Epidemic Encephalitis in 1924,[2] recently annotated in THE LANCET,[3] the question of the relationship of the virus of herpes febrilis with that of encephalitis is again considered In 1920, C Levaditi and L Harvier first recorded the successful transmission to the rabbit of a virus from a fatal case of encephalitis This virus was carefully studied and found to be identical in all respects with the virus of herpes febrilis Other observers reported, in all, six further transmissions to the rabbit, using brain or cerebro-spinal fluid from human cases of encephalitis, and these viruses were also shown to be immunologically and histologically similar to that of herpes Levaditi therefore suggested that the causal agent of epidemic encephalitis was identical with that of febrile herpes, except that the virus of encephalitis had a greater affinity for the central nervous system than that of herpes Doubt has been thrown on this view by several workers, because the few successful transmissions we have mentioned were the only ones recorded after very numerous attempts had been made to produce the disease experimentally Furthermore, the virus of herpes is very easily transmitted to the rabbit by corneal or dermal scarification, or by intracerebral injection of herpes material, and it seems doubtful if these few successful experiments could justify the conclusion that the virus of herpes is the causative agent of encephalitis Moreover, the isolation by S Flexner of an identical virus from the cerebro-spinal fluid, taken from a case of neurosyphilis with no evidence of epidemic encephalitis, casts still further doubt on Levaditi's contention In the recent outbreak in Sheffield, numerous attempts were made to transmit the virus of epidemic encephalitis to rabbits and mice from human material, and also to try to demonstrate the presence of its toxin All these attempts were negative, and the production of experimental encephalitis was not accomplished Parallel work done by J R Perdrau, and described in the index of the Report tends, however, to support Levaditi's contention Perdrau found that the brains of immune animals in the fresh state did not neutralise the virus of herpes in vitro, but after being kept a week or two in 50 per cent glycerine in saline, disease. This typhus-like fever was confined almost entirely to those who lived on mouse-ridden farms, or dealt with mouse-infested grain. Wheatland concluded that it was probably transmitted by some ectoparasite of the mouse. Fletcher and Lesslar's original observations on non-contagious typhus, and their careful review of the literature, will now, it is hoped, meet with the reward such thorough work deserves—a sharper look-out in the tropics for continued fever with exanthem (the rash, they note, is very easily missed in dark skins), and a quickened interest in its ætiology.

MENTAL HYGIENE AND MIGRATION

THE United States of America are unique in the enormous number of foreigners who desire to enter the country; during the first 22 years of this century the tale of immigrants was nearly 18,000,000. Thus the Government has to face in an acute form the economic fact that the more the newcomers to any community the greater the number who will become a charge on the public treasury. The department most interested in immigration is, naturally, the Public Health Service, for it has to bear the burden not only of caring for those immigrants who, unable to adapt themselves to their new environment, become mentally or physically ill, but also of many of the evil results of their presence among the existing population. Since 1891 it has been required by law to examine the physical and mental condition of arriving aliens, and its opinions carry great weight in shaping the policy of the Federal Government. In 1922 the Service began an exhaustive research into the relationship between the migration of peoples and mental health, and the results of their preliminary inquiries are set out in a pamphlet by Dr. Walter L. Treadway,[1] who has had many years' practical experience as a psychiatrist.

In order to study foreign immigration from the standpoint of mental health, Dr. Treadway fully realises that it is necessary to know the methods adopted by communities to relieve distress. These methods, though they evolve with time, are always deeply rooted in tradition and custom. He therefore traces the history of public relief from its beginnings in mediæval England and Europe, through its development in the early American settlements, to its present-day forms in the States. In successive chapters he outlines the growth of workhouses, prisons, and reformatories, and the evolution of institutions for the care of the insane and the mentally deficient, and discusses the early treatment and prevention of mental disorder. In "Glimpses of European Ethnogeny" he surveys the exceedingly complex history of migrations in Europe, with the consequent intermingling of language, folk-lore, and customs, and describes Dr. D. G. Brinton's classification of races, on which is based that adopted by the Immigration Service in 1907. After this comes a detailed survey of immigration during the last ten decades and of the evolution of immigration laws. In considering the psychopathology of racial groups he agrees with Kirby that the Celtic stocks are more prone than any other to develop intoxication psychoses, the Irish ranking first in alcoholic disorders. The Malayic stock seem more liable to develop traumatic conditions, sharing with the Anglo-Americans the unenviable distinction of being more likely to be sent to mental hospitals when not actually insane than any other racial groups. Syphilitic brain disease is least of all in the Anglo-American, while ranking high among Indio-Eranic, Simitic, Negritic, Lettic, Finnic, and Chaldaic stocks. The Teutons and Celts seem to specialise in mental disorders due to senile and cerebral arterial changes, while Tartaric and Hellenic peoples head the list for disorders associated with faulty mental adjustment. Mental disease, when it occurs, is most often benign among Malayic, Anglo-American, Chaldaic, and Simitic immigrants, and the Anglo-American, Tartaric, and American-Indian rank highest for those disorders due to abnormal personal make-up. Mexican, Irish, and German are the three races most often debarred for mental disorder at the immigrant examination.

The difficulties are great of forming an adequate psychiatric opinion on the scanty data afforded by a ship surgeon's report and an interview with the alien who is asserting his right to enter the country, supported by his friends and relations. These difficulties are the burden of the last three chapters of the report. The onus of proof is thrown on the doctor, but he is aided by the enormous mental stress involved in the examination on which the immigrant's fate hangs. The under-average and unstable generally arouse suspicion in the preliminary inquiry, and are put back for further test. Few are ever certified without three complete examinations, and any alien debarred by a board of special inquiry has the right of appeal. A formidable machine, largely sentimental in its origin, is set in motion to stay deportation and land the excludable alien, and subterfuges are often employed. Mentally disabled aliens may land on filing a bond providing against their becoming public charges, and the war period produced a large crop of temporary landings that have become permanent. As Dr. Treadway says, a method has yet to be devised whereby the doubtful mentally disordered immigrant or the potential "misfit" will be prevented from entering America. The need for it is shown by the high proportion of mental disease among foreign-born persons living in the United States. Transport companies could obtain sufficient data to enable them to refuse passage to such aliens as are most likely to become public charges or to be sent back at the expense of the company which brought them. The Immigration Act of 1924, with its penalties for the introduction of aliens suffering from frank disease, affords a starting-point. Dr. Treadway points out that the cost of an adequate examination service would not amount to the expense the companies now incur in caring for detained and deported aliens. He recommends that legislation should include a clause binding the companies to support all aliens who become a charge on the public within five years of their landing, including repatriation and the provision of an attendant when necessary. Such an Act should certainly deter shipping companies from transporting aliens whose mental stability is reasonably in doubt.

CHEMISTRY OF CARDIAC CONTRACTION

AN extract of the right auricle of the dog's heart exerts a stimulating effect on the isolated heart muscle of the rabbit, increasing the amplitude of the muscular contractions, accelerating the rhythm, and even initiating contraction in muscle in a condition of standstill. This was shown by J. Demoor in 1923.[1] More recently[2] the same investigator has made alcoholic extracts of different parts of the heart of the rabbit and tested their relative capabilities in stimulating to increased mechanical response the isolated auricles of the same species. Extracts of the sino-auricular nodal tissue, of the right auricular muscle, and of the left auricular muscle, were investigated in this manner. The isolated right auricle of the rabbit beats rhythmically in a bath of oxygenated Locke's solution, and it was found that the addition of the extract of nodal tissue, and to a smaller extent that of right auricular muscle, exerted definitely positive inotropic and chronotropic influences on the auricular beats. An extract of left auricular muscle was without action. The isolated left auricle of the rabbit shows infrequent irregular contractions when placed in oxygenated Locke's fluid, and it was found that the nodal tissue extract acted specifically on this tissue, converting the spasmodic irregular responses into those of apparently normal rhythmic tolerance, and it was found that the dose could be reduced or the carbohydrate intake increased without ill-effect Acetonuria and acidosis diminish as sugar begins to disappear from the urine, and a case is described in which, after doses of over 75 mg had been given, the acidosis was much lessened at the end of the second day, although it was necessary to starve the patient because of vomiting Synthalin was found to be of no greater value than insulin for diabetic gangrene, and insulin treatment is considered advisable where *an operation is necessary, a gradual* change to synthalin can be made afterwards On the other hand, some patients intolerant to insulin have been treated successfully with synthalin, and in certain cases in which a sugar-excretion of 100 g fell *only to 50 to 60 g* under the influence of insulin, the glycosuria was almost abolished by synthalin The fact that the action of this drug is not so rapid as that of insulin is sometimes advantageous, and in cases where large injections of insulin are impracticable *synthalin is preferable both from the point* of view of cost and simplicity On the other hand, Frank and Heyn point out that synthalin is unsatisfactory for the treatment of coma, as it works too slowly and toxic doses must be given in order to prevent a collapse of carbohydrate metabolism The drug, they say, is still a long way from being ideal, as it does not allow of the patient having a diet sufficiently generous as to be satisfying From the account given it is impossible to be at all sure that synthalin is of a similar constitution to insulin, and it seems that the new drug can only be of use in certain selected cases

TROPICAL TYPHUS

During the late war epidemic typhus occurred on an appalling scale in parts of Europe and Asia It is a disease which follows in the track of famine and destruction, and it is so contagious that in the days of Murchison few or none of the staff of fever hospitals escaped infection, whilst Osler records that during a period of 25 years in Ireland it caused the death of nearly *half the 1200 medical men attached* to institutions Typhus rarely occurs, however, in countries where the climate is hot all the year round, and so is little known to medical men in the tropics The more interest, therefore, attaches to careful observations[1] recently made by Dr William Fletcher and Dr J E Lesslar, who have recognised in the Malay States a continued fever with exanthem, which they have named Tropical Typhus, and which, they believe, extends far beyond the limits of the Malay Peninsula Tropical typhus, as they describe it, differs essentially from the great epidemic disease, the symptoms are the same, and there is a positive Weil-Felix reaction in both, but the epidemiological features are entirely *different It has a very low* infectivity and mortality, patients may remain at home without infecting their families, and it is unusual for more than one person in the same household to have the disease Fletcher and Lesslar have noted many records of outbreaks of mild, non-contagious typhus in different parts of the world where epidemic typhus does not occur—notably Brill's disease (1898) in New York, where it is rarely fatal and never contagious A similar type of mild non-contagious typhus has been described by Yersin (1906) and Vassal (1908) in Indo-China, Smithson (1910) in Queensland, Conor and Bruch (1910) in Tunis, MacNaught (1911) in South Africa, McKechnie (1913) and Megaw (1921) in Kumaon district of Himalayas, Maxy and Havers (1922) in Alabama, Hone (1923) in Adelaide, Sinclair and Maxy (1925) in Rio Grande Valley, Clearkin (1925) and Anderson (1925) in East Africa and Nairobi, and Megaw, Shettle, and Roy (1925) in Central India In none of these outbreaks could careful observation implicate lice as the vectors, in some of them a tick appears to have been possibly to blame They have been grouped together among the typhus fevers by Megaw, but he separates them from the far more severe group of louse-typhus (*exanthematicus*), tick-typhus (Rocky Mountain fever), and mite-typhus (tsutsugamushi) The first and milder group comprises Fletcher and Lesslar's tropical typhus—one disease under many names in many countries In the Malay cases lice could not have been the vectors, infection with the virus was connected in some way with open uncultivated grazing land, and no lesions, such as those caused by mites in tsutsugamushi, could be detected in the skin of either European or Asiatic patients It appears probable that in Malayan typhus the vector is a tick, and Fletcher and Lesslar appeal for the help of entomologists in solving the riddle of the ætiology of tropical typhus

During the late war Weil and Felix (1915) cultivated from the urine of a typhus patient, in Constantinople, an organism of the *proteus* group which was agglutinated by the man's own blood, and also by the blood of other persons suffering from typhus They employed this organism in diagnosis, and called it X 2 Later they found that a similar bacillus, X 19, was agglutinated in higher dilutions than X 2 This strain, X 19, is that now employed in the Weil-Felix reaction, which is regarded by all competent *authorities as a specific test for typhus* fever Fletcher and Lesslar stress the importance of this reaction in the diagnosis of tropical typhus In *some of the outbreaks of mild non-contagious typhus*, noted above this reaction was reported as positive, in others it was negative In the Malayan cases it was always positive They considered these contradictory results as probably due to the use of different strain of *B proteus* in different parts of the world, and accordingly they obtained strains from colleagues in India, Sumatra, and England for cultivation and comparison In fact, the records of the culture characters of the *B proteus* strains used by the several workers do not tally, and show plainly that the respective strains could not be each the same X 19 *Their investigation*[2] *shows that the diversity of strains which pass under the name of B proteus* X19 makes it imperative to carry out careful control tests when working with an unknown culture It is unjustifiable to conclude that a patient is not suffering from typhus because his blood fails to agglutinate an unproven culture If the Weil-Felix reaction be positive, the result can easily be checked by the testing of healthy controls A serum dilution of 1-200 is the limit, they consider, above which agglutination gives positive evidence of typhus They record the important observation that there were two serum-groups of Malayan cases one group gave positive agglutination only with the anindologenic (Kingsbury) strain of X 19, and the other group gave positive agglutination only with *the indologenic* strain of X 19 from the National Collection The two groups appear to be equally common, and show hardly any difference in course and symptoms Neither group is contagious nor spread by lice Attempts to infect guinea-pigs failed, probably because the blood of the patients was not obtained *at any early stage* Dr Andrew Balfour had drawn their attention to the report of F T Wheatland[3] on an outbreak of non-contagious typhus-like fever at Toowoomba, Queensland *This disease* very closely resembled Malayan tropical typhus in its 12 or 14 days' fever, severe headache, macular rash (like that of typhoid, but more profuse), defervescence by quick lysis or crisis, and mortality of 2 per cent It was not carried by lice, and the Weil-Felix reaction was invariably positive There had been a plague of mice on the farms in the Toowoomba district, and *when the human disease* appeared these rodents were dying in great numbers The farmers linked these phenomena, and called the illness mouse-conclusion—namely, that histamine-like bodies are liberated locally The latency of reaction in this type of cutaneous stimulation is explained by the assumption that whereas in freezing, burning, or "stroking" (in a case of urticaria factitia) the cells are suddenly stimulated or damaged, the effects of ultra-violet irradiation are gradual and continuous and the liberation of histamine-like bodies is probably slow and continuous likewise In the fourth article Lewis and Grant discuss the anaphylactic skin reaction and succeed in shedding new light upon some of its features Their experiments were all carried out on a subject susceptible to fish (herring) who was found to be 170 times more suceptible to extract of fish than to histamine (1 in 3000), to which his response appeared to be normal From 6 lb of herring a substance resembling nucleic acid was eventually isolated, and with this substance the same anaphylactic phenomena could be obtained It is suggested as a result of this investigation that "the anaphylactic poison acts on the skin by liberating in it a histamine-like substance" The final article in the series is by Ronald Hare, and is an independent investigation on the same lines as the others above, of the vascular reactions of the susceptible skin to protein Working in the inoculation department of St Mary's Hospital, London, Hare compared the reaction to histamine and to specific proteins in two subjects susceptible to horse-serum and one susceptible to pollen The work seems to have been carefully done; his conclusions confirm the work of Lewis and his colleagues and go to show that a specific protein in a susceptible subject induces the production of histamine-like bodies to which the observed phenomena—local capillary dilatation, increased permeability, and reflex dilatation of neighbouring arterioles —are due These five papers, as will be obvious, contain information and opinions of great interest both to the dermatologist and the physician

SMALL-POX IN THE NORTH

THERE is no abatement in the epidemic of mild small-pox in the North of England, the number of cases notified from the county of Durham during the last few weeks averaging about 250, 27 different sanitary districts being involved

At the request of the chairman of the North-East Durham Joint Hospital Board and of medical officers of isolation hospitals in that board's area, a conference was called last week by Dr T Eustace Hill at the Shire Hall, Durham, to consider the epidemic and the best means for dealing with it It was agreed that the existing accommodation for small-pox in the county of Durham is utterly inadequate to deal effectively with the present epidemic, and that so long as a large proportion of the county is unprotected by vaccination it was almost impossible to control the spread of the disease, owing to the mildness of the cases, which resulted in medical advice not being sought early, the occasional non-recognition of the disease by the practitioner, and the indifference of the community to its spread Neglect of vaccination, it was pointed out, was incurring an enormous expense on the county, the treatment and isolation of cases costing the local authorities alone well over £1000 a week, and the interference with trade was serious The following resolutions were adopted —

That, in the opinion of this conference, the present epidemic of small-pox would not have occurred if the stringency of the Vaccination Acts had not been weakened, and that prompt vaccination or revaccination of susceptible persons is of the utmost importance if the present epidemic of small pox is to be brought under early control, and that if such vaccination or revaccination was secured, small-pox in the county would be stamped out within three months

That, in the opinion of this conference, hospital authorities of districts where the available accommodation is inadequate for the prompt isolation of all cases of small-pox, should utilise, as a temporary measure, their ordinary isolation hospitals for the treatment of small-pox, where such hospitals are suitably situated for the purpose, and make arrangements with adjoining sanitary authorities for the treatment of their ordinary infectious cases in the adjoining hospitals a pooling arrangement being instituted both as regards the isolation of cases of small-pox and cases of ordinary infectious diseases

That if in any district there is available accommodation for small-pox cases in convenient empty buildings, arrangements should be promptly made for the use of these buildings for the isolation of small-pox cases, and that local hospital authorities should also consider the advisability of at once erecting temporary hospital accommodation to enable them promptly to isolate all cases occurring

That the medical officer of health for each sanitary district should communicate with every medical practitioner in his district, calling his attention to the urgent importance of keeping a careful look-out for all suspicious cases of rash and of at once acquainting the medical officer of health of such cases and that a copy of the monograph of Dr McConnel Wanklyn, entitled "The Accurate Diagnosis of Small-pox," should be issued by the medical officer of health of each sanitary district to every medical practitioner practising in that district

The conference concluded by urging upon the Ministry of Health the importance of amending the Vaccination Acts with the object of making vaccination more general and efficient, as vaccination affords the quickest, most scientific, and most economic means of preventing and arresting outbreaks of small-pox

CIRCUMCISION AND CARCINOMA

UNIVERSAL circumcision has many advocates, but they seldom make use of a rather impressive line of argument which has lately been put forward by Dr A L Wolbarst, of New York Dr. Wolbarst thinks it probable that removal of the foreskin of all infant boys would prevent at least 2 per cent of cancer in the male, and brings authoritative statements and interesting figures to support his reasoning "All writers on penile cancer are agreed," he says, "that phimosis constitutes the predominant ætiologic factor in the production of penile cancer" It not only provides the soil from which the growth may spring, but also furnishes and retains the irritating secretions which may call it into being Although he recognises that urethral discharges, syphilitic lesions, polypoid vegetations, ulcers, and trauma may be the starting-point of malignant disease, he regards phimosis as mainly to blame for 85 per cent of cases of cancer of the penis Practically all male children, he points out, are born with a phimosis, and the condition often persists throughout life Everyone knows that even where the foreskin is easily retracted, it is hard to prevent accumulation of urine and smegma, which may set up chronic irritation, and Dr Wolbarst is unimpressed with the suggestion that carcinoma never develops where the foreskin is freely movable, since benign precancerous lesions occur on the foreskin whether it is retractible or not The risk of developing penile cancer is by no means inconsiderable Although uncommon compared with some other varieties of carcinoma it nevertheless comes second in frequency, according to Dr Wolbarst, amongst cutaneous cancers, and is generally said to account for between 2 and 3 per cent of all malignant tumours in the male Although its prevalence has been estimated by some observers at only 1 per cent, he states that the consensus of opinion, as represented by the most recent literature, is that 2 per cent is not too high an assessment If it could be shown that universal circumcision would remove this cause of death and disability there would be an excellent case for adopting it as a prophylactic measure, for although it is conceivable that local irritation does nothing more than determine the site of an inevitable cancer, it is reasonable in the light of present knowledge to make such local irritation as infrequent as possible As circumcision is practised by large communities it should be easy to ascertain whether it does prove a complete safeguard against penile cancer Unfortunately, it is not very easy to collect figures from the official mortality statistics in this country because they give no particulars about religious belief, but Dr Wolbarst says that "students of cancer are agreed that penis cancer rarely if ever has been recorded among activity Prof L Haberlandt, in a series of five papers in the *Zeitschrift fur Biologie* and *Pfluger's Archiv*, has recorded his independent observations on similar experimental lines in the case of the frog We have already drawn attention to this work,[3] and it will be remembered that Ringer's fluid in which the sinus tissue has been beating for some time becomes activated in the sense that the fluid will cause an increased amplitude of contraction and an increased rate of contraction when brought into contact with the frog's isolated ventricle perfused by Straub's method The fluid was inactive in those cases in which the contractions of the sinus tissue were feeble or entirely absent Further, contracting auricular tissue was impotent to activate the fluid in which it was contracting, as was also the rhythmically stimulated tip of the ventricle The production of metabolites, therefore, could not be invoked as the cause of the phenomenon Furthermore, the active substance is produced by the sinus after the addition of ergotamine to the bath, and this fact makes the supposition that the effect observed might be due to the liberation of Loewi's "accelerating substance" improbable Positive results were also obtained in the case of the contracting ventricular base, so that the production of this substance seems to be intimately connected with the presence of Purkinje tissue Haberlandt has made some observations on the chemical nature of this "automatic stuff", he finds it to be soluble in alcohol, dialysable, and insoluble in ether He has obtained positive results in about 66 per cent of the experiments in which the "sinus-basis Ringer" was used and in about 50 per cent of those experiments in which alcoholic extracts of the nodal tissue were employed This fact, taken into consideration along with the independent observations of Demoor on the mammalian heart referred to above, makes it desirable that further work should be done along the same lines Worthy of special study would be the comparative effects of alcoholic extracts of various parts of the cardiac musculature on the rate and on the diastolic volume of the isolated mammalian heart beating under rigidly controlled conditions

THE M O H AND HIS AUTHORITY

The medical practitioner is concerned in local government not only as a ratepayer but on account of the steady encroachment of municipal operations upon the field of his own activities It is therefore worth his while to take every opportunity of examining how the work of these bodies is done, and in Mr. E D Simon's book[4] he will find it clearly and frankly stated Mr Simon, having been Lord Mayor of Manchester and a Member of the House of Commons, writes with authority on the management of public affairs and, breathing as he does the spirit of divine discontent, his account of a council's work is anything but dry It must not be assumed that his dissatisfaction leads to wholesale condemnation of local government, on the contrary, the council receives his blessing for the quality of work it manages to do, hampered by legislative restrictions, party strife, trade interests, and confusion of tutored and untutored counsel He points to weaknesses in administrative organisation, lack of coordination between committees (which really means between the departments of a corporation) and the absence of any official or group of councillors whose main function would be to foster and ensure the beautification of a city and the enlightenment of its people He compares our local government service with the civil service and with the German system to the disadvantage of the former—perhaps because his knowledge of the others is less intimate His experience as chairman of the Housing Committee lends special importance to the chapter on house-building by local authorities Of the many debatable points raised in this provocative book we join issue with Mr Simon on his contention that a medical man is usually a bad administrative officer and that, in order that a medical officer of health may escape becoming too rusty on the medical side to supervise the medical work of his own department, he ought to be subordinated to a lay administrator of the best civil service type We see his point and sympathise with his objects, but the disadvantages of the method he suggests would outweigh the advantages On the whole, Mr Simon seems a little touched with the doctrine of the superman and also inclined to think that when difficulties exist any change would be an improvement His book will therefore appeal especially to the young, which is all in its favour But everybody interested in local government should read it

INJURY TO THE SKIN

A recent issue of *Heart*[1] contains five original papers bearing on the mechanism by which the skin reacts to stimuli The first of these summarises the work of Sir Thomas Lewis and R T Grant on the reaction of cutaneous capillaries to the injection of histamine, and goes on to show that if the skin be so injured that œdema or erythema are produced, its vessels become refractory—for a time at least—to similar or allied stimuli, which in control areas will still produce definite and specific vascular effects Good grounds are given for postulating a mechanism of cutaneous defence in which the local liberation of histamine, or some similar substance, plays a vital part Lewis and Grant regard the refractory stage thus induced as a phenomenon of the cutaneous vessels rather than as an attribute of the epidermal cell, it cannot, therefore, be compared with the mechanism of muscle-cell fatigue In the same article Lewis also reports on his study of the actions of heat, cold, ultra-violet rays, adrenalin, and pituitrin, on areas which have previously been rendered refractory by histamine He found that none of these agents altered the so-called histamine flush until the refractory stage had passed off Applying the available facts to the study of pathological conditions such as the reticular configuration of erythema ab igne on the shins and the production of telangiectases from old X ray burns, he claims that these vascular abnormalities originate in a prolonged phase of "refractoriness of vascular tissue" In the succeeding article Lewis and Y Zotterman, of Stockholm, record their observations on a case of annular œdema secondary to infective endocarditis and explain the configuration of the eruption on the same basis A nodule arising round a presumed embolic focus was seen to spread concentrically outwards, and as it spread the centre of the raised circular erythematous patch would clear, thus giving rise to an annular figure In this involuted central area the refractoriness, induced by the virus and giving rise to the phenomenon of flushing and œdema might be considered to have passed away, but it was still present at the periphery and would remain there until the ring ceased to enlarge—i e., until the virus had been completely diluted or neutralised This interesting conception is supported by the behaviour of two advancing refractory rings when they meet It was seen—and it is, of course, a recognised fact—that these rings never pass through each other, the advance of both peripheries is suddenly checked and a variety of gyrate and polycyclic figures result The substance of this new and important conception can be summarised in the authors' own words "All forms of acute or relatively acute local œdema of the skin are due to injury of that skin, the injury leading to a reaction of the cells of the skin, whereby histamine-like substances are liberated To these substances the vascular reaction, vasodilatation and increased permeability are directly due" The same workers are responsible for the third article in this series, which is devoted to the mechanism of the skin reaction to ultra-violet rays and leads to the same

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCIV.—TREATMENT OF PATIENTS WITH HIGH BLOOD PRESSURE

There is more than a verbal difference between the treatment of high blood pressure itself and of patients with a raised blood pressure. High blood pressure has become a fashionable ailment, sometimes even an obsession, among the public, so that some people go about constantly speaking and, therefore, probably thinking continually of their "blood pressure," and ascribing to its evil influence symptoms really due to other factors. Further, the mental worry induced by knowledge of the possible results of hyperpiesia raises their blood pressure, and hence a vicious circle results, which demands treatment of the patient by sensible optimistic encouragement and bromides. High blood pressure is a manifestation of some underlying disorder—metabolic, renal, dietetic, toxæmic, infective, or psychological—and, though it may be reasonably regarded as responsible for subsequent arterio-sclerosis, renal fibrosis, and cardiac failure, many, if not most, of the symptoms found in persons with abnormally raised blood pressure, and in common usage regarded as due to it, can be better explained as either concomitant effects of the underlying cause or of the resulting or complicating arterio-sclerosis, renal or cardiac disease (*vide* The Lancet, 1926, ii., 1203). It is far more important to treat the underlying conditions or causes just mentioned than to concentrate on reducing the height of the blood pressure, which to some extent is a compensatory mechanism, for to bring it down rapidly and considerably may only make the patient, if, indeed, he was one before, worse. In 1901 Osler published a paper with the wisely paradoxical title, the Advantages of a Trace of Albumen and a few Tube Casts in the Urine of Men over Fifty Years of Age, and in 1912 he wrote on High Blood Pressure, its Associations, Advantages, and Disadvantages. Prophylactic measures in the *initial stages* are, of course, the most effective means of treatment.

Preventive or Prophylactic Measures

A periodic overhaul once or, perhaps, twice a year, such as the wise are accustomed to submit to at the dentist's hands, is an insurance against chronic disease, and is particularly desirable for those with a family history of high blood pressure and its effects. The discovery that the blood pressure is rising steadily or is considerably above the normal makes it essential to review the conditions of life so as to obviate causes connected with occupation, environment, diet, and infection. A hard-working and hard-living man of affairs must relax and reduce the stress and strain of his existence, he must learn to play, to take real holidays and frequent days or week-ends off, to follow hobbies, and avoid overeating, especially excess of meaty foods and their extracts; it is indeed a good, if not popular, rule to stop eating before the appetite is completely satisfied. Regular exercise within his powers should be encouraged. The moral is moderation in all things and freedom from strain of every kind, bodily and mental. To warn a person against worry is easy, but such advice is more helpful when backed up by a prescription for a bromide mixture to ensure some measure of philosophic calm in occasional emergencies. A search must be instituted for any chronic focus of infection in the teeth, tonsils, accessory nasal sinuses, gall-bladder and appendix, prostate, and indigestion and intestinal disorder should receive due attention. A tendency to obesity, especially about the menopause when endocrine deficiency may play a part, should be controlled.

The Management of Patients with fully established High Blood Pressure

The treatment of a patient with fully established high blood pressure depends on wise direction based on personal knowledge of the individual, which may give a clue to the important ætiological factor at work. Of the several possible factors more than one may be concerned, and a right decision on this problem, which may be far from easy, should be more within the power of the regular medical attendant, who knows all the circumstances, than of anyone else. The general principles outlined in the last paragraph hold good, especially encouragement of the patient and emphasis on the share that his cooperation plays in his future. Moderation should be the keynote of treatment, which, it may again be insisted, should be not so much of the supernormal blood pressure as of the patient's manner of life. The blood pressure should not be taken frequently, and it is usually advisable not to communicate the exact figure in millimetres of mercury, as it is easy to breed hypochondriasis by information that the pressure has gone up so many points. Although the treatment of nephritic patients with high blood pressure is different from that of simple hyperpiesia, it may be worth while to quote the perhaps exaggerated aphorism ascribed to the late Dr. W. H. Dickinson that "the great danger of chronic nephritis is that someone will find it out and try to treat it," for too energetic measures may do much harm by knocking down the patient at the same time as the blood pressure.

Diet can easily be too severely restricted; although an exclusive milk diet, as in Karell's cure (2–3 pints daily), may be useful for a few days, especially when the patient is in bed; the food supplied should be sufficient from a caloric point of view, and any risk of semi-starvation must be avoided. The general practice is to cut down the protein, and to allow some white meat, chicken, and fish, but to proscribe red meat, a distinction making little or no difference to the patient's condition. In the light of some American observations of an increased uric acid content of the blood in about 40 per cent of the cases of hyperpiesia, it would appear probable that a diminished protein and purin diet would be mainly of value in patients showing evidence of such disordered protein metabolism and of gout. Clear soups, meat extracts, sweetbread, strong tea and coffee, are best avoided; vegetables and fresh fruit are advisable, and may be useful in providing vitamins and in preventing constipation; but a free carbohydrate diet must be curtailed if it causes obesity or dyspepsia. On the whole, excess of food is probably rather more deleterious than the special quality of the constituents; the diet should be simple and sufficiently varied to avoid monotony. The statement that table salt raises the pressure is open to doubt, and in the absence of cardiorenal complications and dropsy a salt-free diet is more troublesome than useful. It may be noted that recently large doses of calcium or potassium chloride have been advocated as a means of lowering high blood pressure. A moderately restricted intake of water has usually been advocated on the ground that increased volume of the blood imposes more work on the heart and raises the blood pressure; on the other hand, free drinking of waters, as at spas, though not exclusively there, is sometimes followed by a notable fall of blood pressure; the difficulty is to determine beforehand what patients will react in this favourable manner. Although there is not any evidence that alcohol directly raises blood pressure, its generally depressing and degenerative influence on the tissues renders strict moderation highly advisable. Tobacco is usually regarded as undesirable for patients with high pressure, and it certainly causes an immediate though transient rise of blood pressure, followed by a fall to or below normal. But in confirmed smokers in health the blood pressure tends to be low, and as tobacco-smoking commonly has a soothing influence it would appear

Mohammedans and Jews, who practise circumcision in early life as a ritual measure." Among 3,000,000 Jews in the United States cases of penile cancer should be encountered from time to time if the 2 per cent rate of incidence holds good, yet although other forms of cancer are at least as common in Jews as in Gentiles, he says that the records of Jewish hospitals do not seem to mention cancer of the penis except as occurring in their non-Jewish patients Thus in two Jewish hospitals in New York not a single case of this disease is recorded amongst 958 consecutive cases of male cancer If Dr Wolbarst is right in his conclusion as to the comparative freedom of the circumcised, his argument for universal circumcision is a strong one If, on the other hand, he is misinformed about the rarity of penile cancer in Jews and Mohammedans it should be easy to prove him in error It is to be hoped, therefore, that practitioners will place on record any cases in which they have seen the condition in Jews or Gentiles circumcised in infancy

THE ROCKEFELLER FOUNDATION

A bald statement of the activities of the Rockefeller Foundation during the year 1925, for which the report has just been issued,[1] would consist of a long catalogue classified in just over 20 sections This in itself would not be without interest and certain items demand special notice, but what is perhaps more instructive is to observe the trend of policy of this organisation as indicated in the president's review Mr George E Vincent points out that the increase in the number and resources of privately endowed foundations—notably, but not exclusively, in the United States of America—raises pertinent questions as to the place of these agencies in the social order and their relation to the work of governments It is stated elsewhere in the report that 631 formal applications for aid had to be refused during the year 1925 "The types of assistance requested did not fall within the scope of its (the Foundation's) activities as determined by its present politics," for "the Foundation does not make gifts or loans to individuals, nor contribute to the building or maintenance of churches, hospitals (except as certain hospital features may be included in plans for medical education), and other local institutions, nor support campaigns to influence public opinion on social or political questions" The positive side to such negative statements of policy is furnished by the catalogue already mentioned, some of the details of which may now be chosen for comment In the field of public health where the private funds come into relation with the tasks of governments, the Foundation has adopted the policy of working only with and through governments Its International Health Board will lend a hand only on the invitation of an official agency, and it is kept constantly in the foreground that the task of protecting a community against disease must be accepted by a government as its own primary responsibility On these lines in 1925 official anti-hookworm measures involving the treatment of nearly 1½ million people were carried out and yellow fever has been practically eradicated from the Americas With regard to its interest in medical education the Foundation's policy is based on the fact that the backbone of any public health measure is formed by the medical profession, and hence the necessity of emphasising the "preventive idea" even in undergraduate days The dangers attached to this are, of course, realised, and in particular it is pointed out that if a curriculum is to be permeated with this "preventive idea," there must exist "a curriculum of the right sort to be permeated" Hence the support shown by the Foundation to medical schools in many lands, and the expenditure of approximately three million dollars in 1925 on this item alone Realising that "medicine, both curative and preventive, whether it be considered as science or art, quite obviously depends directly on psychology, biology, chemistry, and physics," the Foundation is supporting certain activities in connexion with mental hygiene and psychology, and is showing an interest in biology Here a special form of aid calls for separate notice, for the Foundation has granted 350,000 dollars to be spent over a ten-year period in support of the production of "a world memory for biology" which is the president's way of describing a huge abstracting enterprise to cover the estimated 40,000 articles dealing with biology in 5000 different journals each year In other fields the activity of the Foundation continues to show progress In China the Peking Union Medical College carried on as usual in 1925 despite the local distractions and the policy of transforming "the College gradually into a Chinese medical centre with a Chinese staff and ultimately a Chinese board of trustees in complete control" is being carried out effectively The nurse is also observed with interest by the Foundation, and the president's review contains a good summary of the difficulties now presenting themselves in the nursing profession where the attractions offered in the public health field are said, in America at any rate, to be luring the nurse from the smaller hospitals and from private work The Foundation stands aside in the controversy, devoting itself to the training of leaders in the nursing profession in different parts of the world This point alone could be expanded to demonstrate the policy of the Foundation in most of its work, but sufficient has been said to indicate how it is moving Its watchwords, in the language of its president, are "coöperation not rivalry, response not propaganda, economy not speculation, temporary aid not continued subsidy, official responsibility not usurpation of authority, a permanent gain not an ephemeral exploit"

The Services.

ROYAL ARMY MEDICAL CORPS

Maj W J E Bell and Capt T H Twigg, are secd for service under the Colonial Office

Capts G F Carr and B H C Lea-Wilson (Prov and remains secd) to be Majs

Capt P L C Carrier retires, receiving a gratuity

REGULAR ARMY RESERVE OF OFFICERS

The undermentioned Cols having attained the age limit of liability to recall, cease to belong to the Res of Off : O K Morgan, late R A M C and Hon Brig -Gen C G W. Hunter

TERRITORIAL ARMY

Maj O H Mavor (late R A M C, T A) to be Maj, supern for service with Med Unit, Glasgow Univ, Sen. Div, O T C

Lt H W M Williams resigns his commn

Lt J R. Wheeler (late R F A, Spec Res) to be Lt, supern for service with Med Unit, Belfast Univ , Sen Div, O T C

J H Strahan to be Lt , supern for service with Med. Unit, Belfast Univ , Sen Div , O T C

INDIAN MEDICAL SERVICES

Lt.-Col R F Baird officiates as Inspector-General of Civil Hospitals, United Provinces Lt -Col H H Broome, Principal, King Edward's Medical College, Lahore, to be a Member of the Governing Body of the Punjab State Medical Faculty, vice Khan Bahadur Syed Nazirhussain, resigned

DEATH IN THE SERVICES

Deputy Inspector-General Henry Manton Murray Sedgwick, R N , died at Southsea on Dec 23rd, aged 86 He entered the Royal Naval Service as assistant surgeon in 1863, and saw foreign service on the East Indies station During the Abyssinian war he was medical officer of the Naval Brigade (mentioned in dispatches, promoted to surgeon, and received the Abyssinian Medal) In 1882 he was fleet surgeon in H M S *Inflexible*, at the bombardment of Alexandria (Alexandria clasp, the Khedive bronze star, and the Order of the Medjidieh) He retired in 1892

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCIV.—TREATMENT OF PATIENTS WITH HIGH BLOOD PRESSURE.

THERE is more than a verbal difference between the treatment of high blood pressure itself and of patients with a raised blood pressure High blood pressure has become a fashionable ailment, sometimes even an obsession among the public, so that some people go about constantly speaking and, therefore probably thinking continually of their "blood pressure," and ascribing to its evil influence symptoms really due to other factors Further, the mental worry induced by knowledge of the possible results of hyperpiesia raises their blood pressure, and hence a vicious circle results, which demands treatment of the patient by sensible optimistic encouragement and bromides High blood pressure is a manifestation of some underlying disorder—metabolic, renal, dietetic, toxæmic, infective, or psychological—and, though it may be reasonably regarded as responsible for subsequent arterio-sclerosis, renal fibrosis, and cardiac failure, many, if not most, of the symptoms found in persons with abnormally raised blood pressure, and in common usage regarded as due to it, can be better explained as either concomitant effects of the underlying cause or of the resulting or complicating arterio-sclerosis, renal or cardiac disease (*vide* THE LANCET. 1926, *ii.*, 1203) It is far more important to treat the underlying conditions or causes just mentioned than to concentrate on reducing the height of the blood pressure. which to some extent is a compensatory mechanism, for to bring it down rapidly and considerably may only make the patient, if, indeed, he was one before worse In 1901 Osler published a paper with the wisely paradoxical title, the Advantages of a Trace of Albumen and a few Tube Casts in the Urine of Men over Fifty Years of Age, and in 1912 he wrote on High Blood Pressure, its Associations, Advantages, and Disadvantages Prophylactic measures in the initial stages are, of course, the most effective means of treatment

Preventive or Prophylactic Measures

A periodic overhaul once or, perhaps, twice a year, such as the wise are accustomed to submit to at the dentist's hands, is an insurance against chronic disease, and is particularly desirable for those with a family history of high blood pressure and its effects The discovery that the blood pressure is rising steadily or is considerably above the normal makes it essential to review the conditions of life so as to obviate causes connected with occupation, environment, diet, and infection A hard-working and hard-living man of affairs must relax and reduce the stress and strain of his existence, he must learn to play, to take real holidays and frequent days or week-ends off to follow hobbies, and avoid overeating, especially excess of meaty foods and their extracts, it is indeed a good, if not popular, rule to stop eating before the appetite is completely satisfied. Regular exercise within his powers should be encouraged The moral is moderation in all things and freedom from strain of every kind, bodily and mental To warn a person against worry is easy, but such advice is more helpful when backed up by a prescription for a bromide mixture to ensure some measure of philosophic calm in occasional emergencies A search must be instituted for any chronic focus of infection in the teeth, tonsils, accessory nasal sinuses, gall-bladder and appendix, prostate and indigestion and intestinal disorder should receive due attention A tendency to obesity, especially about the menopause when endocrine deficiency may play a part, should be controlled

The Management of Patients with fully established High Blood Pressure

The treatment of a patient with fully established high blood pressure depends on wise direction based on personal knowledge of the individual, which may give a clue to the important ætiological factor at work. Of the several possible factors more than one may be concerned, and a right decision on this problem, which may be far from easy, should be more within the power of the regular medical attendant, who knows all the circumstances, than of anyone else. The general principles outlined in the last paragraph hold good, especially encouragement of the patient and emphasis on the share that his cooperation plays in his future Moderation should be the keynote of treatment, which it may again be insisted, should be not so much of the supernormal blood pressure as of the patient's manner of life The blood pressure should not be taken frequently. and it is usually advisable not to communicate the exact figure in millimetres of mercury. as it is easy to breed hypochondriasis by information that the pressure has gone up so many points Although the treatment of nephritic patients with high blood pressure is different from that of simple hyperpiesia, it may be worth while to quote the perhaps exaggerated aphorism ascribed to the late Dr W H Dickinson that "the great danger of chronic nephritis is that someone will find it out and try to treat it," for too energetic measures may do much harm by knocking down the patient at the same time as the blood pressure.

Diet can easily be too severely restricted, although an exclusive milk diet, as in Karell's cure (2–3 pints daily) may be useful for a few days, especially when the patient is in bed, the food supplied should be sufficient from a caloric point of view, and any risk of semi-starvation must be avoided The general practice is to cut down the protein, and to allow some white meat, chicken, and fish but to proscribe red meat, a distinction making little or no difference to the patient's condition In the light of some American observations of an increased uric acid content of the blood in about 40 per cent of the cases of hyperpiesia, it would appear probable that a diminished protein and purin diet would be mainly of value in patients showing evidence of such disordered protein metabolism and of gout. Clear soups, meat extracts, sweetbread, strong tea and coffee, are best avoided; vegetables and fresh fruit are advisable and may be useful in providing vitamins and in preventing constipation; but a free carbohydrate diet must be curtailed if it causes obesity or dyspepsia On the whole, excess of food is probably rather more deleterious than the special quality of the constituents; the diet should be simple and sufficiently varied to avoid monotony. The statement that table salt raises the pressure is open to doubt, and in the absence of cardiorenal complications and dropsy a salt-free diet is more troublesome than useful. It may be noted that recently large doses of calcium or potassium chloride have been advocated as a means of lowering high blood pressure A moderately restricted intake of water has usually been advocated on the ground that increased volume of the blood imposes more work on the heart and raises the blood pressure, on the other hand, free drinking of waters. as at spas, though not exclusively there, is sometimes followed by a notable fall of blood pressure, the difficulty is to determine beforehand what patients will react in this favourable manner Although there is not any evidence that alcohol directly raises blood pressure, its generally depressing and degenerative influence on the tissues renders strict moderation highly advisable Tobacco is usually regarded as undesirable for patients with high pressure and it certainly causes an immediate though transient rise of blood pressure, followed by a fall to or below normal. But in confirmed smokers in health the blood pressure tends to be low, and as tobacco-smoking commonly has a soothing influence it would appear unnecessary to deprive the patients of this solace unless they are conscious of any ill-effects, such as cardiac pain or irregularity

Rest and Exercise—High blood pressure is undoubtedly reduced by rest in bed, as, indeed, it normally is in the recumbent position, but this is a temporary result and with a return to ordinary life it resumes its previous character Still a full night's rest is always beneficial, and occasionally a whole day in bed does good. The heart may thereby be relieved of strain, but the underlying factors of the raised blood pressure are not likely to be influenced except, perhaps, psychologically Rest in bed may become necessary for subsequent myocardial failure, but this is another story Exercise of various kinds, especially in the fresh air, according to the patient's powers and never so extreme as to cause dyspnœa or other distress, is advisable both bodily and mentally Failing opportunity for exercise in the open, breathing and other forms of indoor exertion have their place, as has massage in certain circumstances

Baths—On *a priori* considerations hot baths would seem suitable, but their value has not escaped some criticism for they raise the systolic pressure slightly while lowering the diastolic pressure to a greater degree, and thus increase the work of the heart Cold baths are undesirable, as they raise the blood pressure Patients are often greatly improved and their pressures lowered by a visit to a spa where facilities for several forms of treatment freedom from worry and the psychological effect of change play a part Residence in a warm climate, a prescription more easy to give than to carry out, exerts a beneficial influence

High frequency currents lower the pressure for a time, *diathermy* is said to keep the pressure down much longer, so that eventually monthly treatments are sufficient to maintain a reduction permanently down to a level appropriate for the individual patient Ultra-violet rays are also stated to have a similar effect, in this method, as in diathermy, the mode of action is not certainly known, but Sir Thomas Lewis's work suggests that a histamine-like body is liberated from the damaged skin *Lumbar puncture* and *venesection* at once reduce the pressure for a short time, and may be useful in the emergencies of hyperpietic crises, but their effect is very transient

Drug treatment is the least important, and it is significant that so many have been advocated. Bromides are, on the whole, the most effective, and, of course, act by relieving mental strain and anxiety Of the vaso-dilators, mannitol nitrate and erythrol tetranitrate are stated to have a more prolonged effect than the commonly used trinitrin The effects of nitrites are fugitive only, but occasionally they relieve headache and insomnia Hippurates and guipsin have not come up to their initial reputation, and benzyl benzoate and extract of liver, the effect of which is said not to be due to histamine or choline, are on their trial Calomel either in minute (1-20th gr t d s) doses or in larger quantities (½ to 1 gr) once a week appears to benefit the patients Constipation should be prevented, but the intestinal antiseptics have been generally disappointing Iodides have been largely used, but they do not have any direct effect; it has been suggested that their action is indirect by stimulating the thyroid, but the disappointing effect of thyroid extract by the mouth does not render this explanation convincing Ovarian, or corpus luteum extract, has been recommended for the menopausal high blood pressure Drugs, such as aconite and antimony, which reduce blood pressure by depressing the heart, should not be used, but chloral in 5 gr doses is sometimes useful

PRESERVATIVES AND COLOURING MATTER IN FOOD

THE NEW REGULATIONS

WHEN the Minister of Health made the Public Health (Preservatives, &c, in Food) Regulations on August 4th, 1925, he directed that they should not come into operation as a whole before Jan 1st, 1927, and that parts of them should be still further postponed Recently, on Dec 10th, he amended the Regulations, partly in points of substance and partly in respect of the dates of their operation, to which reference will be made presently It will be recalled that the Regulations of 1925 followed in the main the recommendations contained in the final report of the Departmental Committee (presided over by Sir H C Monro) appointed in July, 1923, to inquire into the use of preservatives and colouring matters in food

Prohibitions and Permissions

The Committee's principal conclusions were that preservatives should be prohibited in all articles of food or drink offered for sale, whether manufactured in this country or imported, but an exception was made in favour of specified proportions of sulphur dioxide and benzoic acid The Committee went on to say that the sale of any preparation as a food preservative should be declared illegal unless accompanied by a clear description of its composition and strength and unless the preparation was free from impurities and contained no more than 1/100th part of a grain of arsenic or 1/7th of a grain of lead to the pound It recommended that the use of a copper salt to colour peas or other vegetables should be prohibited and that the Ministry should issue a schedule of non-injurious colouring matters These recommendations were substantially followed in the 1925 Regulations, wherein will be found two important schedules The first of these contained in Part I a list of articles of food and drink which may contain preservative and specified the nature and proportion of the preservative in each case, and in Part II a list of the colouring matters which may not be added to articles of food, the second schedule dealt with the labelling of preservatives and articles of food containing preservative The Regulations define "preservative" as meaning "any substance which is capable of inhibiting, retarding, or arresting the process of fermentation, acidification, or other decomposition of food or of masking any of the evidences of putrefaction," but excluding common salt, saltpetre, sugars, acetic acid, or vinegar, alcohol or potable spirits, herbs, hop extract, spices, and essential oils used for flavouring purposes or any substance added to food by the process of curing known as smoking To this list of permitted substances a recent amendment has added glycerine Local authorities have the duty of enforcing the 1925 Regulations in so far as they relate to the sale of articles of food and preservatives, the Customs authorities are naturally concerned as to imported articles of food It will now be an offence to manufacture or sell any article of food which contains an unauthorised preservative or colouring matter It will also be an offence to violate the labelling requirements, though there are exceptions in favour of sales in restaurants and certain other cases Comment was made upon the permitted preservatives when the Regulations were first published some 15 months ago[1] The recent amendments have modified the permissive provisions in respect of fruit and fruit pulp of all kinds, jam, marmalade, and fruit jelly, and crystallised glacé or cured fruit (including candied peel) These items are in part reclassified, with a restatement of the maximum permitted proportion of sulphuric dioxide in each case.

[1] THE LANCET, 1925, ii, 413

Dates of Operation

The Committee recommended, and the Minister of Health conceded, that manufacturers and importers should be allowed a period of grace to clear existing stocks. The Minister states that the previous postponement of operation has not succeeded in meeting the requirements of the parties concerned but he finds himself unable to grant any extension. He suggests that local authorities may consider it desirable to refrain from initiating prosecutions for a few months till stocks are cleared. This is an unfortunate and unconstitutional though possibly convenient course. Penal provisions should not be enacted and brought into force unless and until it is intended that they shall be executed. To give a local power of dispensation will lead to strange discriminations up and down the country. The Ministerial attitude is like that of the Ministry of Agriculture when the Milk and Dairies Order was lately attacked in the House of Lords. Lord Bledisloe's official defence in effect admitted that parts of the Order might be mistaken and extravagant, but said that local authorities would be given a departmental hint not to be too severe. This is the wrong way to legislate. Regulations should not be made more drastic than the circumstances require, nor should they operate until the moment is ripe. The actual dates of operation of the 1925 Regulations (as amended) are as follows: for bacon, ham, egg yolk, and articles of food containing preservative necessarily introduced by the use of preserved margarine in their preservation, July 1st 1927; for butter, cream, and articles of food containing preservative necessarily introduced by the use in their preparation of preserved bacon, ham, egg yolk or cream, Jan 1st, 1928; for articles of food containing preservative necessarily introduced by the use in their preparation of preserved butter, July 1st, 1928; for all other foods, Jan 1st, 1927. It may be added that the Stationery Office is conveniently reprinting the principal regulations of 1925 with the insertion of the recent amendments in the form in which they will now operate.

The Onus of Proof.

It remains to notice certain other matters in relation to the administration of the new law. The desired object is that the prohibitions and limitations in the Regulations should have binding effect in a court of law in proceedings under the Sale of Food and Drugs Acts. That is to say, it should be sufficient for the prosecution to prove that a preservative or colouring matter is present in an article of food in contravention of the Regulations; it should be possible to eliminate the usual conflict of expert evidence on the question whether the amount of such preservative or colouring matter so present is or is not injurious to health. It is doubtful how far this desirable result can be attained by mere Regulation without a fresh Act of Parliament. The Departmental Committee drew attention to an important difference in the burden of proof under the Sale of Food and Drugs Acts and under the Butter and Margarine Act of 1907. In the former case the person charged has to prove his absence of knowledge (in view of Sections 3 and 5 of the Sale of Food and Drugs Act, 1875), in the latter case the onus of proof that the offence is wilful lies on the prosecution. This difference should be adjusted by Parliament. Another point remarked by the Committee was the difficulty of bringing home an offence to the manufacturer. The retailer may escape, though an infringement of the law has been proved, because he is not to blame for the impurity or unwholesomeness of an article. The manufacturer who is responsible is brought within the law by Section 25 of the Sale of Food and Drugs Act, 1875, and Section 20 of the Act of 1899 which allow a defendant to plead that the goods were sold to him with a written warranty. But it has usually been found that the article has passed through so many hands and so much time has elapsed, that prosecution of the manufacturer is useless. As has already been mentioned, the 1925 Regulations penalise not only the sale but also the manufacture for sale, of articles of food which offend against the prohibition or limitation of preservatives and colouring matter. Much may be hoped of this improvement in the law.

PARIS.

(From our own Correspondents.)

Medical Secrecy

Medical secrecy has always been a source of controversy and this is growing steadily more acute because, with the socialisation of medicine, doctors are being asked for more and more certificates about their patients. It is suggested that the time has come to set up some sort of rule to define the medical man's position and Dr. Paul Gallois suggests that the Academie de Medecine should ask Parliament to incorporate statements in the law to the following effect: "Medical secrecy is part of a contract between the doctor and his patient, and the doctor cannot surrender his patient's confidence to any other person. The patient alone can release the doctor from his obligation to maintain secrecy, in which case, however, the doctor is not bound to speak. A doctor must not divulge information given by his patient, except in the form of a certificate, and such a certificate should be sent to the *patient*, who may use it if he wishes and thus takes the responsibility for the facts being made known. Secrecy is not limited to confidential information given by the patient, but extends to everything that the doctor is able to see, hear, or discover if revelation of it might be harmful or merely disagreeable to the patient; this applies even to cases in which the doctor has no wish to be damaging. Short of superior force a doctor must not in his dealings with any person represent two different interests and consequently fulfil two opposite functions. For example he cannot act, at one and the same time, as the doctor treating the case and as the doctor who is in charge of it in some official or expert capacity. He should also avoid treating simultaneously two people whose interests are at variance. If for the good of the community the State has need of medical information, it can obtain it by asking from the patient or his agents-at-law a certificate from the doctor in charge, and the State should also retain the services of medical men for purposes of inquiry where no adequate certificate is obtainable."

Fuso-spirochætosis

Dr. Paul Lafosse and Dr. Jacques Langle, of Vincennes, have reported on 53 cases of bronchitis in which the sputum contained large numbers of fusiform bacilli together with Vincent's spirochæte. These patients have a painful, paroxysmal, noisy cough followed by expectoration of variable quantity; in three cases the sputum had a stale smell—at one time even sickly. Hæmoptysis occurred only eight times and produced no general disturbance, the patients waking up from sleep to find the mouth full of blood. Constitutional symptoms were unusual and no fever was observed. Clinical examination showed only the common signs of bronchitis and slight congestion; X ray examination was nearly always negative, and tubercle bacilli were never found in the sputum, which, however, revealed in the 53 cases a symbiosis between the fusiform bacillus and the spirochæte. Treatment with arsenic always improved the condition at any rate for a time, and removed the association of bacillus and spirochæte. These features of the disease made it easy to correct the diagnosis of pulmonary tuberculosis which had been attached to many of the cases.

Insulin.

Desgrez, Rathery, and Froment, of Paris, classify diabetics treated by insulin in three groups: (1)

those in which insulin only does good so long as its administration is continued, the insulin acting as a substitutive remedy like thyroid extract in myxœdema, (2) those who react badly to insulin, probably because their condition is not determined solely by the pancreas, and (3) those in whom insulin appears to be actually curative, since their improvement continues even when doses are reduced or made less frequent. Without going so far as to speak of true cure, it seems that in the last group of cases there is functional recuperation—partial at any rate—of carbohydrate metabolism, though, of course, the patients have to be carefully watched for fear of relapse.

The Centenary of Laënnec

The ceremonies to celebrate the hundredth anniversary of Laennec's death began at Paris on Dec. 13th with a requiem mass at Notre-Dame, after which the delegates were received at the Académie de Médecine and the Hôtel de Ville. In the evening the President of the Republic attended an assembly at the Sorbonne, held under the presidency of M. Painlevé, Minister for War, and orations on various aspects of Laennec's work were delivered, after which the foreign delegates presented addresses to the President. The colleges and societies of Great Britain were represented by Sir StClair Thomson, Sir John Broadbent, Sir Edwin Bramwell, Sir Percival Hartley, and Prof. William Stirling. The evening's proceedings ended with a speech by M. Painlevé. On the following day visits were paid to the hospital where Laennec received instruction from Corvisart, to the house in rue de l'Abbé Grégoire where he last lived, and to the Carnavalet Museum. In the afternoon M. Herriot, Minister of Education, presided over a formal session of the Académie de Médecine, whilst on the following day there was a reception at the Hôpital Laennec and visits to the Leon Bourgeois Dispensary, and to the Hôpital Necker where Laennec was physician. At the Pasteur Institute Prof. A. Calmette gave an address on the prevention of tuberculosis since Laennec, and the three days' celebration closed with a banquet at the Palais d'Orsay.

Gabriel Petit, in collaboration with Panisset and Kfouri, has succeeded in overcoming the well-known resistance of the horse to tubercle by inoculating bacilli directly into the lung through the bronchi. To produce in the lungs of a horse—and in the lungs alone—tuberculous lesions of slow development and of the human clinical type, is to extend greatly the field of experimental work.

Tuberculous Infection of the Newborn.

Prof. A. Couvelaire during the past five years has had under observation 357 children born of tuberculous mothers and has found that the percentage of stillbirths (which, on the average, was 10.6) is considerably greater in cases where the maternal tuberculosis is severe. At the beginning of his investigations the death-rate during the first month of life was 33 per cent., but in the last series of 126 cases it had fallen to 7.2 per cent., thanks to improvement of conditions, the babies being reared in strict isolation from their mothers. This fact is evidence against the theory that most babies dying in the first month are congenitally infected. It is not less true, however, that certain cases of death from malnutrition, steadily progressive from birth, remain unexplained. Recent research has suggested that side by side with the very rare congenital infection which produces specific lesions there exists a commoner trans-placental transmission of the virus.[1]

At a meeting of the Académie de Médecine on Dec. 7th this question was generally discussed, and Prof. L. Bernard pointed out that the filterable forms of virus obtained by Couvelaire have not been proved the actual cause of tuberculosis in the fœtus. He pointed out that it is still very doubtful if there is such a thing as placental transmission of tuberculosis, and advised that a conservative attitude should be taken towards the problem so as to avoid creating false impressions in the public mind.

MEDICINE AND THE LAW

An Abortive Prosecution

On Dec. 22nd the stipendiary magistrate at Clerkenwell police-court dismissed a summons against Prof. E. B. Verney, of University College, for "unlawfully having in his possession a certain dog, to wit a small mongrel wolfhound, the property of Frederick Smythe, knowing such dog to have been stolen." No opportunity arose for Prof. Verney to make his reply to this charge, the magistrate dismissing the summons on the preliminary ground that there was no evidence of possession. Mr. Roland Oliver, K.C., who appeared for the defendant, protested vigorously against a society putting up a nominal prosecutor to attack Prof. Verney and the University College which carried on vivisection under a statutory licence. He described the proceedings as an abuse of the court, and asked for costs. The magistrate presumably agreed, for he awarded five guineas costs and stated that he did not think the prosecution should have been launched. He did not further enlarge upon the reasons for his decision; indeed, he disclaimed any intention of pronouncing upon the merits of the case. If, however, there are those who infer that an experienced and disinterested magistrate would regard the interposition of the society as evidence rather of a desire not to pretermit an opportunity for propaganda than of a fair and reasonable resort to legal process, their impression will probably not be removed by reading the report of the case published in another column (p. 50). It happened that the copy of the *Times* which contained an account of this abortive prosecution of a research worker by a body which had not prepared itself to prove the elements of its accusation, also contained an account of the valuable results achieved by medical research at Mill Hill in the direction of rendering dogs immune from distemper.

Medical Evidence of Insanity

In dismissing the appeal of Cecil Roodhouse, convicted at Leeds Assizes of the murder of his sister, the Court of Criminal Appeal on Dec. 20th placed the usual legal limitations upon the value of medical evidence of insanity. It had been argued on behalf of the appellant that, being defended under the Poor Prisoners Rules, he could not obtain expert evidence of his insanity, but that the opinion of the local doctors appeared to indicate epilepsy as well as adolescent insanity. Lord Hewart used the occasion to point out that the responsibility of deciding the question of insanity rests with judge and jury at the trial, not with the medical expert. "There are those who would let it rest with the opinion of a doctor, but at present the evidence of doctors is subject to the good judgment of the jury; we have not yet come to the time when a man can get off by getting a doctor to go into the witness-box." The rather notorious difference between what are called the legal and medical views of insanity was further illustrated by Lord Hewart's subsequent observations. "It has now been said that, had the judge at trial collected all the available evidence of possible insanity and put it cumulatively before the jury, the verdict would have been a different one. Probably it would; but then the judge would not have been doing his duty, because he is expected to put the case to the jury according to the proper practice of law." And so we see once again that in a given case the medical profession may be perfectly satisfied that it detects the presence of mental disease. Yet the legal profession—or, at any rate, the judges who express the official legal view—may tell the jury to reject all evidence of abnormality as justification for a verdict of "not guilty" unless the weight of such evidence is so overwhelming as to turn the scale at that point where, according to a legal and in a sense an artificial standard, criminal irresponsibility at last begins.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

A BRIEF SURVEY OF 1925

AT the wish of the Ministry of Health the reports of medical officers for the year included a survey of progress made during the preceding five years This, naturally resulted in their late issue in a number of cases, but many on which we have had the opportunity of commenting certainly indicate substantial progress in public health measures in spite of hampering financial restrictions Big schemes, of course have had to wait

Environmental.

The *housing* shortage is still acute and the districts able to provide for the natural increase of the population are fortunate. Private enterprise houses are only built for sale There is much subletting of municipal houses, and there are no houses being built for the poorest-paid workers. Slum clearances are held up by the shortage. The new Bill for rural housing is arousing the hope of better accommodation for the country labourer

Sewage disposal and the prevention of the pollution of rivers have made progress and in many districts the bio-aeration system appears to meet with approval As regards *refuse disposal*, there have been many complaints of the dumping of the refuse of London and other towns in the country districts, somewhat mitigated by the Ministry's suggestions for the regulation of tips.

As regards *water-supply*, chlorination has ceased to be a temporary measure and the competition for river waters seems to point to the need for a national survey and allocation of all the sources of water-supply. The exact meaning of the presence of the colon bacillus in waters and the influence of seagulls on its introduction are matters of interest.

The country appears to be waking up about *smoke abatement*. Classes for stokers are being held, and persuasion, education, and advice by experts are becoming recognised as a better way than prosecutions. Efforts are being continued to find a satisfactory smokeless domestic fuel, and thus to acquire the desired result without running counter to the national desire for an open fire. Local Bills now contain powers to stop the emission of grit. There is much encouragement of the use of gas and electricity Manchester, through its regional committee, may yet show England the way to deal with industrial smoke

The campaign against *conservancy closets* in towns is becoming more active, and even Hull is now taking a hand

Food.

The use of preservatives such as boric acid appears to be going on up to the time-limit, and the report of the borough analyst for Salford shows that skimmed milk masquerading as cream ’ may be taken as typical of many food sophistications. The meat regulations are doing good, and in several counties demonstrations have been held at the abattoirs for the instruction of sanitary inspectors in meat *inspection* There is a general expression of opinion in favour of the extension of the regulations to cooked meats

Graded milks make slow progress but have a useful educational effect. Clean milk *competitions* are numerous and many municipal institutions give the preference to Certified and Grade A (tuberculin-tested) milk. There is no lessened frequency of tuberculous milk and udders, but good results are hoped from the reintroduction of the Tuberculosis Order on Sept. 1st, 1925 Some counties have appointed whole-time veterinary inspectors, others have appointed inspectors under the Diseases of Animals Acts, while the remainder have done nothing A few rural district councils have arranged for regular veterinary inspection of their milk herds

Infectious Diseases

The Schick and Dick tests and subsequent immunisation are being increasingly used for hospital staffs for the prevention of cross-infection, and for the abolition of outbreaks in institutions Vaccines are being suggested for measles scarlet fever, and pneumonia. The prevailing type of scarlet fever is so mild that removal to hospital is being discouraged The stay in hospital is being shortened, and it is becoming common to call in the aid of the oto-rhinologist. Small-pox has been prevalent in many districts, but usually of the mild type, and much difficulty is reported in securing the vaccination of contacts Typhoid is referred to as almost extinct, and a large proportion of the few remaining cases are attributed to shell-fish

The reports of the *venereal disease* clinics show that syphilis is less prevalent and that attendances are improving though probably not many districts approach the low Edinburgh default of 11 3 per cent Most clinics now provide facilities for daily irrigation and intermediate treatment Owing to the reluctance of women to attend the clinics special facilities are provided in many districts for women and children

In the reports on *tuberculosis*, the most frequent wants mentioned are increased provision for advanced cases and for bone and joint tuberculosis The results of training for vocations have usually been disappointing Many counties and districts are now instituting complete orthopædic schemes, including all forms of crippling in addition to tuberculosis with a central hospital and out-patient feeders

Influenza was more prevalent during 1925 than in the preceding year *Encephalitis lethargica* was less so but the case fatality was, as a rule, greater. The need for special educational institutions for the survivors from this disease is being considered As regards *cancer*, early treatment still holds the field, and to this end facilities for obtaining a consultant's opinion free of charge have been arranged by some authorities. The need for research into the ætiology of *rheumatism* and for the provision of institutions on open-air lines for affected children is being more and more recognised

Maternity and Child Welfare.

Many reports refer to high maternal and neonatal mortalities Antenatal hygiene is gradually developing into real preventive midwifery Municipal maternity homes hold antenatal clinics and in some cases make attendance at the antenatal clinic a condition of admission A considerable number of authorities have appointed obstetricians to conduct the antenatal clinics In many districts courses of lectures by specialists on the danger signals in pregnancy and antenatal work are arranged for the midwives. The need for more maternity hospitals is more or less general, especially in view of present housing conditions.

Ophthalmia neonatorum still takes its toll of eyesight, owing to the failure to secure efficient treatment promptly. Light treatment is being tried fairly extensively both for rickety and debilitated children and for tuberculosis In the latter disease opinions as to its value vary from guarded to enthusiastic. Arrangements for the operative treatment of tonsils and adenoids are being improved and in many districts all children are admitted to hospital or nursing home for the operation.

Administration

Much progress has been made towards the coördination of the public health services so as to avoid overlapping and to secure one medical and nursing staff for children from birth to the school-leaving age. Attempts are being generally made to secure the pooling of isolation and small-pox hospitals in county areas, as it is found that in these days of motor transport one efficiently staffed and equipped hospital is infinitely better than the large number of unsatisfactory small hospitals which have been the rule up to now

The need for the education of the public in the essentials of healthy living, and especially in the right choice of food and in the new ideals of obstetric care, is stressed in most of the reports.

SCHOOL MEDICAL SERVICE

A SURVEY OF 1925

IN spite of great financial difficulties the service showed real progress in every branch of its work during the year Including routine and special cases, 2,619,350 children, or more than half of those in attendance at school, were examined, an increase of nearly 200,000 over the previous year The school staff now consists of 1140 whole-time doctors—or one to every 8500 children—780 specialists employed on ophthalmic, aural, anæsthetic, X ray and orthopædic work, 584 dentists, and 4520 school nurses The cost of this service in 1924–25 was £1,300,317, or about 2 25 per cent of the cost of public elementary education—not a high premium for health insurance

Preventive measures, designed to teach the child the way of personal health and to lay the foundations of national well-being, are gaining ground The educative nature of this work is now recognised by the closer union of all administrative and executive workers The Director of Education, the school-teacher, the attendance officer, and the school doctor each take a share in the work of child welfare, and the team-work now possible is bringing us nearer the goal The effective help and interest of the teachers, without which the medical work could not go on, has in places gone so far as to provide convalescent homes, country holidays, and funds for clothing

In view of the importance of the pre-school years, on which so much of nurture depends, it is gratifying to note the increasing cooperation between the public health and the school medical services, medical supervision will soon be continuous from birth to adolescence, for in some districts—e g, Leicester—the factory surgeons take their part in the roster In districts such as Acton (Dr G J Thomas) and Willesden (Dr G Buchan), defects discovered at the welfare centre receive treatment at the school clinics, and it has been noted that children who have come from the centres present a much lower incidence of defects (even allowing for more efficient parents) than those who have not been under such supervision. Fuller advantage is being taken of the activities of voluntary care committees and associations, notably those for mental welfare, which have established many occupation centres for low-grade mental defectives, and the Invalid Children's Aid Association which restores many ailing children to health by convalescent treatment The Central Council for the Crippled Child is now an integral part of the mechanism for dealing with physically defective children in 122 educational areas A complete scheme includes ascertainment, provision of remedial facilities, and provision of efficient after-care, it is under this last heading that organisers of physical education, beside suggesting and supervising the physique and morale of the normal child, can render valuable service by arranging for remedial and re-educative exercises

Measures to prevent debilitating and crippling influences have been developed along various lines The most successful results are to be seen in the open-air schools, the present accommodation of which is still inadequate for the needs of the country The cost per child at one of these schools averages £30, against £12 per child per annum in the ordinary elementary school, but this extra cost is fully justified by the permanency of the good results obtained, Dr G A Auden, for instance, found that 89 per cent of the 748 Birmingham open-air scholars maintained the improvement which all the children show when first admitted Nursery schools have worked wonders for younger children, as may be seen from the report of the Margaret MacMillan School at Deptford

Ninety-six additional school clinics have been opened during the year—there are now only five education authorities without—113 authorities have extended their existing provision Treatment of visual defects is more general and comprehensive than any other Of 184,533 cases of defective eyesight and squint, 80 per cent were treated It is now realised that infancy is the time for effective treatment to begin, and much valuable work has been done among pre-school children, witness Dr R R Garden's orthoptic treatment of Bristol infants The increase in facilities for in-patient treatment for the removal of tonsils and adenoids has resulted in the disuse of 11 school clinics for this purpose, the work having been transferred to hospitals where the child can remain all night In Nottingham the aural surgeon, Mr H B Tawse, uses artificial sunlight as a general tonic on children for a few weeks prior to operation Ionisation is found as a rule to be the most rapid and efficient method of treatment for various forms of ear disease, and 26 additional authorities made arrangements for this during the year Mr A G Wells (L C C) has extended ionisation to include a number of cases complicated with attic, mastoid, and other diseases Dr Alfred Friel (L C C) gives a clear outline of the method in Sir George Newman's Report for 1925 (page 49)

The facilities for dental treatment have been extended in most areas, and 133 new dental clinics were opened, leaving only 28 areas where no provision is as yet made The most effective training for blind children is that given in residential schools, unfortunately their cost is almost prohibitive, and excellent work is being done in special day schools

The difficulty of mental defect is increasingly recognised Mental defectives, says Sir George Newman, are expensive to educate, but they are more expensive to neglect Two Acts of Parliament, if only they were made effective, require the appropriate authorities to deal with such defectives The ideal solution seems to lie in the proper training of the child and adolescent, and the effective control of the adult Much has been done in providing special and residential schools

Encephalitis lethargica showed a fall in the numbers of new cases during 1925, and provision for treatment of after-effects has been made in two wards at the Northern Hospital, Winchmore Hill, London Valuable work has been done by school doctors in bringing to light the sequelæ of this disease, residential treatment is generally regarded as the only successful way of dealing with these cases, few of them respond to treatment as mentally defectives Some other infectious diseases have been unusually prevalent Small-pox was rife in parts of Durham, Yorkshire, Northumberland, and Nottingham, of 2139 children of school age who developed small-pox only five are stated to have been successfully vaccinated prior to the attack

The hygiene and sanitation of many of the schools throughout the country leaves much to be desired, and must be tackled soon if preventive medicine is to become effective Our knowledge of the normal physiology and variations of normal childhood is at present limited, as is our knowledge of the ætiology of many of the common diseases of childhood The relationship of heredity, environment, climate, and diet to physique and character is but imperfectly understood, and the exceptional opportunities of school medical work for solving these difficulties are being widely utilised Dr G Woolham has been studying the physical capacity of Manchester schoolboys and has worked out formulæ for assessing physical fitness Nutrition of school-children and sleep in relation to housing conditions and diseases have been investigated by Dr M Gross, of Stafford Thyroid diseases and iodine deficiency have been investigated by Dr. M Fraser. of Cumberland who maintains that goitre is but one of the lesser manifestations of iodine deprivation. Dr W M Ash of Derbyshire sounds a warning note on iodine medication through a public water supply Dr. Middleton Martin of Gloucester administers 1/10 gr. of iodine in tablet form for goitrous children, while Dr. Dunstan Brewer of Swindon uses collosal iodine Dr. E H M. Milligan. of Glossop in his investigation found that rheumatism is more prevalent in goitrous children. These and other researches on thyroid abnormalities are being correlated and analysed by Dr. Percy Stocks, of University College, and Dr Maurice Campbell of Guy s Hospital. who hope to summarise their findings in the near future.

Rheumatism with its protean manifestations is most prevalent during the school years of childhood and Dr C J Thomas (L C C) computes that there are 10 000 rheumatic children in London alone. In many districts school doctors are working in collaboration with practitioners consultants and University colleagues in continuous efforts to solve the many mysteries of this disease In Bristol Dr J Morrison has outlined the influence of environment in causing rheumatic heart disease: Dr A P Thompson (Birmingham) has been working along somewhat similar lines; and Dr R H Vercoe (Chelmsford) finds parental history the most important causal association and dampness of the house of less importance In Cheshire Drs A. V Stocks Marjorie Grant. and W J. McIvor are working along some original lines bearing on this disease and Dr E H Snell of Coventry. and Dr Mary Weston of Leicester have investigated chorea in relation to rheumatism These individual outlines will be finally worked into the complete mosaic by a committee of investigation appointed by the British Medical Association.

These are only a few of the original and scientific investigations carried out by school doctors during 1925. but they serve as an augury for the future, and an indication of the vitality that permeates the whole organisation.

MENTAL HOSPITAL REPORTS.

THE *Devon Mental Hospital* at *Exminster* had 1216 patients on its register at the end of 1925. an increase of 35 on the year before, and the accommodation for women is becoming strained. The death-rate was 6 63 per cent . the lowest since 1899. The cause of death was verified by autopsy in 63 per cent of cases The recovery rate was 37 4 per cent and among the private patients alone 47 4 per cent There were 21 cases of typhoid, with two deaths Systematic search revealed one carrier, and as the disease has shown no abatement the staff and patients are all being inoculated and the Widal test is being done on cases selected at random to test the efficacy of this protective measure There is still a certain amount of dysentery General paralytics are now being treated by induced malaria, and renal function tests are carried out on all subjects of operation. The value of luminal in epilepsy has been investigated Sixteen operations were performed in the new operating theatre by the visiting surgeon, and the ophthalmic surgeon saw a number of cases of eye disease and eyestrain. Thirty-eight patients were examined in the new X ray room · all accident cases are radiographed The new dental department has been visited by over 200 patients It is excellent to learn that a fortnightly out-patient clinic has been opened at the Exeter Dispensary and that patients discharged from the hospital can report here for after-care The clinic is run in coöperation with the Exeter City Mental Hospital 113 patients were on parole, and whole day bus excursions picnics ·and blackberry and daffodil parties were greatly enjoyed by other patients About 140 went to a travelling circus, and the time-table of dances, dramatic entertainments, &c occupies three pages of the report The Hobart mixer has effected such economy that it has been possible to dispense with one kitchen and an assistant cook The vegetable-slicer has resulted in a saving of £22 on marmalade alone. The floor and walls of the central kitchen have been tiled, and still more aluminium ware has been introduced. reducing considerably the expense of breakages. The annual report is a specimen of the work turned out from the hospital's printing office. and is illustrated this year by two half-tone plates Patients are also employed in the weaving-room, where blankets tweeds, and serges are made; in mat-making, net-making, knitting, and tailoring

A cinema and wireless apparatus and a special bath for hydrotherapy have been installed The visiting Commissioners remark on the canvas rest which has been devised for the comfort of patients in the continuous bath, and add that "the spirit of progress which has been noticed on former occasions . has been admirably maintained "

The difficulty of finding suitable candidates for the nursing staff is increased by the lack of proper quarters Nine more of the staff obtained their M P.A. certificate during the year

The annual report of the Asylums Committee of the *City of Birmingham* deals with two mental hospitals At *Winson Green* there were 743 patients on Dec 31st. 1925 The recovery rate was 45 6 per cent . a slight increase on the previous year. and well above the average figure. Recovered patients were sent out on trial before discharge. and received money grants where necessary. The death-rate was 7 7 per cent . the lowest since 1851 Post-mortem examinations were made in 63 8 per cent of the deaths In addition to spring influenza there were four cases of infective diarrhœa Malarial treatment of general paralysis has resulted in improvement, but not in cure. 65 per cent of the patients are employed in the house. grounds and farm. Parole and short leave were granted to a large number A wireless set was installed in the hall and a gramophone in each of the wards At the end of 1925 no less than 64 5 per cent of the nurses were fully qualified in mental nursing The visiting Commissioners remark that "the conditions prevailing here afford an example of what can be done in an old institution under an administration based on modern methods . . and a sympathetic regard for the comfort of those under care"

At *Rubery Hill and Hollymoor Mental Hospital* there were 1691 patients at the end of the year The recovery rate was 39 15 per cent . but 68 03 per cent of the direct admissions were discharged recovered or relieved The death-rate was 6 32 per cent ; autopsies were performed in 74 7 per cent An outbreak of typhoid occurred in the spring and affected three nurses and two patients Every female patient was tested serologically and 13 carriers were detected. The outbreak was controlled by vaccination and segregation The hospital has a visiting surgeon, rhinologist gynæcologist, and dentist About 830 patients are provided with employment in the wards, grounds, and workshops Twenty-nine nurses obtained their M P.A. certificate during the year. The hospital shares with Winson Green the services of a welfare visitor who visits all patients on trial and some of those discharged and who also works in the wards Considerable attention is paid to the elimination of toxic foci, and good results have followed this line of attack.

The *Wilts County Mental Hospital* had 1168 patients in residence on Dec 31st. 1925, an increase of 110 during the year. The death-rate was 6 9 per cent . and autopsies were performed on 82 per cent The general health was good, but there was a heavy incidence of dysentery—33 cases with 12 deaths There was, however, no typhoid The recovery rate was 36 1 per cent All but three of the 84 patients discharged were sent out on probation first, 32 of them with a money grant The committee remark on the attention attracted throughout the county by the idea of out-patient clinics in connexion with mental and general hospitals, and hope that a scheme may mature before long.

There are two mental hospitals in *Kent* At *Barming Heath* there were 1793 patients at the end of the year, owing to the serious overcrowding on the female side a house was rented as a nurses' home. The admission-rate for males, on the other hand, was the lowest for more than 50 years The death-rate was 6 2 per cent, and post-mortem examinations were made in 90 9 per cent of the fatal cases; 20 per cent were over 70 years of age The recovery rate was 36 per cent and the general health was good but for a severe epidemic of influenza in the spring There was one case of dysentery and two of enteric An occupation officer has been appointed, and 65 6 per cent of the male patients are employed Two more workshops, for mattress-making and upholstery, have been opened, and the printing shop extended. Various new forms of occupation have also been introduced for the women, mat-making, hat and glove-making, and basket-making One female ward holds itself responsible for the care and repair of the linen and clothing of the corresponding male ward, and this personal note has interested a number of patients who previously refused to take up any work A large proportion of patients are allowed parole, and three male wards and seven female wards have open doors Cases considered fit for discharge are usually sent out on trial first The Commissioners remark that they are impressed by the efficiency in management and the ardent efforts made by the staff of this hospital to do all that is possible for the welfare of the patients The lighting system is at present unsatisfactory, and it is hoped to instal electricity when finances permit Five wards on the male side are staffed by women nurses, 69 of the staff hold their M P A certificate At *Chartham Down* there were 1182 patients, and, as 171 more beds have been provided by the new blocks, there is vacant accommodation proportionate to the estimated increase in population for three or four years The death-rate was 8 per cent and the recovery rate 47 per cent There was no dysentery and only mild influenza The visiting Commissioners remark that "an earnest endeavour is being made to bring the hospital thoroughly up to date, although a great deal remains to be done" Suitable cases of general paralysis have been treated with induced malaria and others by the Starke method with equally good results A small clinical laboratory is being equipped, and an admission hospital is urgently needed Fifty-three nurses hold their M P A certificate

The average number of patients in the *Roxburgh District Asylum* during the year 1925-26 was 357, including private patients and three voluntary boarders. The recovery rate was 27 per cent and the death-rate 7 7 per cent Post-mortem examinations were held on 18 out of the 28 patients who died There was no serious epidemic or infectious disease Some of the verandahs have been enlarged and a new mess-room for the nurses completed Several patients were sent out on probation before discharge

The *West Riding Mental Hospital* at *Wakefield* housed nearly 2200 patients at the end of 1925 The recovery rate was 16 62 per cent and the death-rate 9 23 per cent. The superintendent points out that the apparent recovery rate is reduced by his practice of excluding from that figure the large number of discharged patients (nearly 40 per cent) who were sent to the care of their relatives without much likelihood of recovery Moreover, no less than 37 per cent of the admissions during the year were to be regarded as definitely incurable He includes among these all general paralytics, for he is not satisfied that any true cure has been produced among these patients, although any form of acute illness will probably cause a remission of symptoms *Post-mortem* examinations were performed on 86 per cent of the 197 deaths, and the results gave a tuberculosis incidence of only 3 per cent, while dysentery and typhoid only occurred in 0 5 per cent each The routine work on dysentery showed how dangerous it is to mix newly transferred cases with patients in residence, as about 20 per cent of them presented a positive Flexner agglutination A good deal of histological research was carried out in the pathological laboratory in addition to the routine work Many structural alterations and improvements were completed, and congestion was relieved by the remodelling of a villa residence for females on parole and of a home for the Stanley Hall boys An operating theatre will be ready shortly Only eight patients were sent out on trial This hospital is one of the pioneers in out-patient work, and 63 new cases were admitted during the year under review It is regrettable, though, that the 12 cases found unsuitable for clinic treatment could not be admitted at once and without certification Nine more nurses obtained their M P A certificate

There are two mental hospitals in Hampshire At *Knowle* there were 1018 patients at the end of last year This included a large number of senile cases and mental defectives, which accounts for the relatively low recovery rate of 22 65 per cent The death-rate was 6 61 per cent, the cause being verified by autopsy in 63 per cent of the total number The general health has improved considerably. The number of deaths from tuberculosis has fallen from 22 in 1922 and 16 in 1924 to 5 in 1925; there were no cases of colitis and only two of typhoid fever Eight carriers have been isolated, and the laboratory investigation is still proceeding All the carriers are now kept isolated The medical superintendent attributes the reduction in colitis to decrease in overcrowding, improved diet, cleanliness, and nursing, and more time spent in the open air A ward has been reconstructed for the treatment of general paralytics by malaria About 60 patients have parole within the grounds, and 30 more are allowed to go outside Three male and two female wards are "open" The infirmary wards have been subdivided so as to provide long-needed admission wards There is a well-equipped laboratory, and one of the attendants is being trained as assistant Four male and six female nurses obtained their M P A. certificate during the year

At *Park Prewett* there were 1153 patients on Dec 31st last There was a recovery rate of 25 69 per cent, reduced by the high percentage of unpromising admissions and the discharge of 40 patients to the care of their friends under Section 79 of the Act The death-rate was 6 16 per cent The general health during the year was good, and there were no epidemics. Parole is granted wherever possible, and many patients are allowed to sit up until 10 P M A consulting surgeon has been appointed, in addition to the consulting ophthalmologist The dental surgeon has treated more than 400 patients Only one patient suffered from tuberculosis, and this disease accounted for two deaths only Verandahs are extensively used in treatment There is a room for biochemical and bacteriological work, and an electrically heated continuous bath It is hoped that the scheme for a new nurses' home will induce nurses to remain longer at the hospital Thirty-five of the staff hold their M P A certificate, nine more having obtained it during the year

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 18TH, 1926

Notifications —The following cases of infectious disease were notified during the week Small-pox, 315 (last week 328), scarlet fever, 1531, diphtheria, 1111, enteric fever, 48, pneumonia, 1316, puerperal fever, 59, puerperal pyrexia, 109, cerebro-spinal fever, 9, acute poliomyelitis, 25, acute polio-encephalitis, 6, encephalitis lethargica, 41, continued fever, 1, dysentery, 6, ophthalmia neonatorum, 113 There was no case of cholera, plague, or typhus fever notified during the week

Deaths —In the aggregate of great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 28 (0) from measles, 5 (2) from scarlet fever, 35 (9) from whooping-cough, 40 (12) from diphtheria 45 (12) from diarrhœa and enteritis under 2 years, and 60 (18) from influenza The figures in parentheses are those for London itself

PUBLIC HEALTH IN THE LOCAL LEGISLATION OF 1926.

IN so far as public health can be promoted by Acts of Parliament, the local are not less important than the general statutes Progressive local authorities take the initiative , the rest of the country follows their example in time In the campaign for public health the local skirmishings ahead of the general front line are always worth study and for this purpose the local Acts of 1926 provide good material The Public Health Act of 1925 greatly enlarged the powers of local authorities, but evidently there is a demand in many places for powers still wider in matters like the protection of food supplies and the prevention of infectious disease. As to food, the local Acts of 1926 furnish frequent instances of the usual clauses prescribing adequate larder accommodation, restricting the handling or cooking of food by infected persons, regulating ice-cream and potted-meat manufacture, and empowering the supervision of the transport of food There are also examples of clauses for penalising the original vendors of unsound food and authorising the search of vehicles, sacks, parcels, &c The Chorley and Guildford Acts prohibit the introduction of inedible fats on premises where food is prepared The Guildford Act prohibits the blowing of meat carcasses and makes food poisoning notifiable Many localities obtained in 1926 a statutory widening of the definition of "infectious disease," the list in the Infectious Diseases (Notification) Act of 1889 being thus enlarged to include such illnesses as measles, German measles, whooping-cough, chicken-pox, scabies, ringworm, and influenza As usual, restrictions have been placed in many places upon Sunday schools and entertainments in times of epidemic Parents are to notify the head teacher of a child's infection The withholding of information from medical officers is frequently made punishable Power is taken to obtain the names of an infected household's laundry, and, at Chorley, to obtain lists of a dairyman's customers Another clause in the Chorley Act authorises the municipality to supply doctors with antidotes At Hackney a medical officer may enter a common lodging-house under warrant There is often a power for the removal from houses of the bodies of persons dying of infectious disease Sufferers from any grave infectious disorder may be removed to hospital at Bristol without a justices' order if the sufferer or his or her parent or guardian consents There is a stronger but not entirely novel clause in the Hackney Act for removing a patient certified to be suffering from pulmonary tuberculosis when his existing accommodation is such that proper precautions against the spread of infection cannot be taken, if "thorough inquiry and consideration have shown the necessity in the public interest for the compulsory isolation of the person so suffering" The order of a metropolitan police magistrate is necessary and may be made subject to independent medical examination Other anti-tuberculosis clauses elsewhere include the disinfection of premises and the special prohibition of handling or cooking food The Colwyn Bay Act (Section 86) and the Margate Corporation Act (Section 78) have identical provisions for demolition orders in respect of stables or cowsheds where animals are kept, on certificate by the corporation's veterinary surgeon that an infectious or parasitic disease has appeared and that efficient disinfection is not possible

There are certain novelties in the local Acts of the past year which have a special value as precedents Bristol has secured a power to make by-laws under Section 157 of the Public Health Act of 1875 for compulsory notification where bathrooms are erected and geysers or other hot-water apparatus installed for the purpose of baths This will be found in Section 86 of the Bristol Act , Section 87 prohibits the erection of any house, building, or structure in streets not formed or sewered, but allows a right of appeal to the magistrates Housing and town planning being closely allied to public health, we may also note that the London County Council has obtained a power to extend the 1925 Housing Act in the direction of commercial accommodation Southend-on-Sea and Margate can now prevent erections on forecourts which mar the local amenities Eastbourne took a notable step towards acquiring the adjacent downs by compulsory purchase, failing agreement Newcastle has obtained town-planning powers over lands already developed Swindon is authorised to set aside parks, gardens, and pleasure-grounds for the exclusive use of boys and girls attending elementary and secondary schools in the borough. In connexion with water-supply it will be found that the Rhymney Valley and Taf Fechan Water Boards are now allowed to make reasonable subscriptions to associations of water authorities and to pay the costs of attendance of members and officers at conferences The latter Board has been given a new power to impose summary penalties for the breach of any order it may make prohibiting sheep-washing (with or without chemicals) in the area including the Taf and its tributaries and the Board s reservoirs The local legislation of 1926 does not make much mention of river pollution, but there are occasional references to the protection of fisheries—e g , to the Dart waters in the Paignton Act, Rumworth reservoir in the Bolton Act, and the Hampshire Conservancy in the West Hampshire Water Act There is a remarkable clause in Section 9 of the Stoke-on-Trent Act authorising the corporation to contract with the owners and occupiers of factories or other trade works for the supply of sewage effluent The contracts are to provide that the effluent shall not be used for any other purpose than for condensation or boiler or other factory purposes or for washing coal or coke on the premises of the person supplied There is mention of the London, Midland and Scottish Railway as a possible purchaser of effluent, apparently in connexion with its canals By way of safeguard the consent of the Ministry of Health is to be necessary to all contracts, and he may impose conditions to prevent nuisance or danger to health , further, a Factory and Workshops Act inspector may bring offenders before a court of summary jurisdiction. The City of London (Various Powers) Act regulates the discharge of offensive liquids (chemical or trade refuse, waste steam, liquid heated above 110 degrees Fahrenheit, crude petroleum, &c) into sewers, and has special provisions for waste pipes conveying acids from premises where chemicals are used The slaughter of animals is prohibited in the City by the same Act Elsewhere there are clauses against offensive trades in the Acts relating to Bristol, Chorley, Colwyn Bay, and Paignton, and against smoke nuisance in those relating to Bristol, Chorley, Halifax, Margate, and Newcastle-on-Tyne These localities, together with Guildford, Southend-on-Sea, and the urban district of Mynyddislwyn are some of the principal pioneers of public health in the local legislation of 1926. In many cases local authorities have already shown the way , others, no doubt, will follow

---

STREET ACCIDENTS AND INSURANCE AT SHEFFIELD The Governors of Sheffield Royal Infirmary have decided to relieve the pressure caused by casualties by providing an entirely separate casualty department, and the scheme has been referred to the medical staff for consideration of details At the meeting at which this decision was taken Mr R W Matthews, who presided, urged that the voluntary hospitals should be given statutory power to recover the cost of insured patients

DOMESTIC SERVANTS AND CONTRIBUTORY SCHEMES An endeavour is being made to induce domestic servants in the 250 parishes served by the East Suffolk and Ipswich Hospital to join the contributory scheme which is already in successful operation It is pointed out that since household servants have not to pay unemployment insurance they are better off than many employed persons , moreover, the Health Insurance Act does not entitle them to free treatment at the hospital By joining the scheme the full facilities of the hospital would be available to them

UNIVERSITY COLLEGE, LONDON, AND A STOLEN DOG

A SUMMONS DISMISSED

AT Clerkenwell Police-court on Dec 22nd 1926, before Mr Dummett, magistrate Dr E B Verney, Professor of Pharmacology at University College, London, was summoned on the charge of having in his possession a small mongrel wolfhound the property of Frederick Smythe, of Doughty-street, W C, knowing it to have been stolen

Mr E D Wetton (for the prosecution) said that the summons was under Section 19 of the Larceny Act, 1861 The owner of the dog would give evidence that the dog was safe in his possession on the morning of Nov 19th, and it was common ground that it was at University College at 12 30 or before without the consent of the owner He submitted that it was not necessary for him to prove that Prof Verney received the dog knowing it to have been stolen, it was sufficient to prove that Prof Verney had good reason to know that the dog was stolen between Nov. 19th and 22nd, and that before it was returned to its rightful owner he remained in possession of the dog, knowing it to have been stolen

Mr Frederick Smythe was the first witness examined by Mr Wetton He said that he had called at University College on the afternoon of Monday, Nov 21st, and had seen Prof Verney, and told him that on the previous Friday, about 11 o'clock, the dog had been stolen from the front door-step Prof Verney had then gone to the end of the paved courtyard and unlocked a place and turned up a light, and after a minute or two had come back and said that he was very sorry, but he could not do anything without the Provost (Sir Gregory Foster), and that he would go and see the Provost When he came back, after some considerable time, he said he was very sorry indeed for all the trouble witness had had and for the long wait, but the Provost had, unfortunately, gone He asked witness to return on the next morning at 10 o'clock, when he saw the Provost and Prof Lovatt Evans, as well as Prof Verney The Provost said that at about 11 30 on the previous Friday they had received a dog somewhat answering the description, and Prof Verney brought up the dog, who recognised his master and went away with him

In answer to Mr Roland Oliver, K C, who appeared for Prof Verney, witness said that he was treated with perfect courtesy by Prof Verney, who showed every sympathy with his loss Prof Verney promised that in the interval between witness's first and second visits to the College nothing should be done with any of the dogs in their possession Witness admitted that the Provost also had treated him with perfect courtesy, and that before going away with the dog he had signed a statement acknowledging the return of the dog, and had added the words "I desire to thank all concerned for the kind and courteous way I have been treated" He had gone away from that interview perfectly satisfied, and had offered to pay for the dog's keep while it was there

Mr Oliver then asked whether the solicitor in this prosecution, Mr E Hayes Jones, had been employed by the witness to do any work before this prosecution and the following facts were elicited —

Witness (answering) No, I have had very little work for a solicitor

Q Did you go to him or did he come to you?

A I went to him

Q Who sent you to him?

A The British Union for the Abolition of Vivisection

Q And they asked you to go to their solicitor?

A I wanted to prosecute, and I considered I had a right to do so I had not legal help at the first hearing, and I wanted legal help, and I wanted financial help

Q And they very kindly sent their solicitor. I suppose they are paying the costs for you, aren't they?

A Yes

Q It does not seem to have much to do with them, does it, whether your dog was stolen or not?

A I think so

Q The Society against vivisection?

A Yes, I lost my dog, and it was taken there for the purpose of vivisection I am as dead against it as they are

Mr Wetton then called Leonard Shaw, an animal boy at University College, who gave evidence as to the arrival of the dog at the kennels

Mr Wetton said that he wanted to tender evidence with regard to a system

The Magistrate You have proved description of the dog, and that they went to the kennel and then came back, and Prof Verney said they could do nothing because the Provost had gone So far as that indicates anything at all, it indicates that the Provost was the person who was responsible

Mr Wetton Prof Verney went to the kennel where dogs were kept, lit a light, unlocked the kennel with a key, and came out again, and I ask you to infer that after the interview with Smythe and the description by Smythe, and that Prof Verney was the person he saw on the 22nd, that Prof Verney was the person responsible He gave Prof Verney a written description of the dog, and Prof Verney did not then say "No, I cannot do anything until next day"; he went to the compartment where dogs were kept, he lit a light, and remained in the kennel for some time, and then came back and said, "I must see the Provost," and then the next morning the dog was returned

The Magistrate · The only inference I can draw is that Prof Verney, desiring to ascertain whether the dog as described was there, went to look, and, assuming that he saw a dog answering the description, he concluded that it was the dog Still, he came back and said "I have not the power, the Provost is the man"

Mr Oliver I do not want it to be thought by anybody that I am contending that there can be no evidence it was stolen; I am very loath it should be suggested that that was the only defence we can have, that Prof Verney was not in technical possession of the dog

The Magistrate I am sitting here as magistrate to do a public duty and to save time where I can, there are other cases to be heard And if the prosecution fails to satisfy me on the essential points in this section, it is my plain duty to say so at once, and without any reference to the merits of the case on either side

Mr Wetton It is quite clear that on that Monday Nov 22nd, the dog was under Prof Verney's control

The Magistrate What evidence is there?

Mr Wetton Because Prof Verney was the person in question Prof Verney was brought to him

The Magistrate Prof Verney sees the dog and says something which shows that somebody else had control If you ask me to say he had it in his possession I cannot I cannot prevent your asking me, but it is no good I dismiss the summons

Mr Oliver You have got discretion, Sir, in the matter of costs and I ask you for the costs of this action Here is a case, I submit, where the law has been abused, deliberately abused, not by the poor old gentleman who owns the dog, but in order to attack Prof Verney This Society is paying his costs He has been put up to do this, and I do not take it that the Society will leave the poor old gentleman to foot the bill for this disgraceful prosecution Being unable to attack the methods of this University College, who carry on experiments under licence and who are in every way absolutely under proper supervision and care, and are thoroughly humane, being unable to attack on the lines they want to attack animal experiments they put up this poor old gentleman to be the nominal prosecutor in a case brought in a way which suggests that Prof Verney has been guilty of receiving stolen property That is their method of getting at Prof Verney. and it is an abuse of the process of this Court It is a perfect scandal that it should have been brought against this gentleman. he is as a matter of fact accused of dishonesty. That is their method I therefore ask you to say Sir that on its merits you give my client some expenses I ask you to say it is not right that this gentleman or the University College shall be put to this trouble to establish what never ought to have been assailed

Mr Wetton So far as the College is concerned. there is a dog which has been stolen and within half an hour of its being stolen it has found its way to the College and is admitted to have been under their control by Sir Gregory Foster It may have to be considered whether we shall have to bring him into Court on a subsequent occasion The dog is stolen for a short time and it is only by great persistence that this gentleman gets his dog back

The Magistrate That is no evidence It might justify taking action by the owner of the dog As you say. a dog is taken away at 11 o'clock, and at 11 30 is in possession of University College One understands that the owner of the dog should feel some resentment and a desire that some investigation should be made but you are not representing the owner; you are representing a Society which rightly or wrongly. takes a strong view on the matter of vivisection and from the evidence under their consideration have launched this prosecution I have no interest in the question whether it is scandalous but whether it is a prosecution which should have been launched seriously by people with a knowledge of legal procedure on the evidence at their disposal. They must have seen that it must fail, because they had no evidence on the vital point of possession I am against you on that view. I can quite imagine that Prof. Verney and all the officials very seriously regretted that they should have been dealing with people who bring dogs to the College in that way. It is quite obvious that their view will be that such inquiries as they may make in future will have to be supplemented by further measures to prevent any such scandal as a dog being taken in this way, and I am sure the hospital authorities will strengthen their methods

Mr Oliver The man from whom they bought this dog was the man they had been dealing with for ten years, a man named Travert He is of very good character. and has never been convicted or suspected of any stealing He had employed an agent and University College are investigating that source and they are horrified at what has occurred

The Magistrate I am glad to hear that because this dog was obtained by a person in the Caledonian Cattle Market Whoever stole this dog took it to the Caledonian Cattle Market and it was purchased by the person who sold it to the Hospital So I am sure now the Hospital know that, they will put their house in order

Mr Oliver They have done so Sir

The Magistrate I do not think this prosecution ought to have been brought because it ought to have been clear that it must fail on the ground of the information I have had I shall give only small costs five guineas costs against the prosecution

At the close of the case Mr Oliver remarked that several times the word ' hospital had been used when obviously it should have been ' college : the two institutions were under separate administration

THE TREATMENT OF CORNS

BY E G V RUNTING

A CORN has been described by Dr P S Abraham as " a localised tylosis occurring in particular situations where there is intermittent pressure from without and solid resistance from within " It is characteristic of a corn that the keratinous cells are moulded into one or more conical horny points The impingement of these stunted cones on the sensitive tissue beneath or even directly on a nerve filament or plexus is the immediate cause of pain These horny indurations may form one or more crescentic shapes conforming to the contour of the bony prominence of a joint The soft corn is identical in structure Whereas the hard corn is caused by the direct intermittent pressure of the leather of the boot the soft corn is induced by indirect intermittent pressure through one toe on another. skin being in direct contact with skin The condition of the skin is relaxed through deficient evaporation of sweat and heat and moisture and reduces it to a sodden or macerated state. Soft corns are often characterised by ring-like indurations round the edges which are the most concentrated part of the growth

It is peculiar to chronic growths of this type that the tissue immediately beneath the apex of the corn is subject to morphological change as a consequence of nature's effort to modify the pressure at this point by creating a sort of sac or adventitious bursa. When this structure exists it has an important influence on the redevelopment of a corn after treatment should this not be adequate The bursa is particularly evident in, although not confined to. soft corns

Prophylaxis

Prophylactic and remedial measures entail consideration of the shape and length of the boot or shoe A straight inner line for the great toe is very important, while sufficient upper leather to give room for the toes to extend is essential. Measurement taken while the person is sitting is misleading. for that position does not allow for the elongation of the foot when standing and walking The shank should fit well up into the arch from the heel to immediately behind the metatarsal heads The stocking should have some cushioning properties, some fine silk stockings are made with woollen feet and should be worn by those who tend to suffer from corns in preference to those with silk or cotton feet Coarse or too hard threads should be avoided, the coarse seams so often found even in expensive stockings may be sufficient to produce corns. especially in children The habit of wearing two pairs of socks or stockings in winter needs careful supervision. since it is often the cause of trouble from induced toe flexion The effects of the occlusion of air when patent leather and rubber shoes are worn may be detrimental nor does the frequent soaking of the feet in hot water which is a habit far too prevalent. have a beneficial effect on feet subject to corns There are some patients who persist in following the dictates of fashion and refuse to alter their type of footwear, even if it is obviously faulty These patients in whom the disorganisation of the skeletal contour is often beyond correction can be relieved only by the regular attention of those trained in manipulation of neglected conditions of the feet

Applications

Advertised remedies for corns usually contain in some form preparation of the active principle of salicylic acid. this is applied either in an ointment. plaster or collodion solution. and with it is generally combined a small quantity of cannabis indica. added for its anodyne effect, although creosote is sometimes used for this purpose. There is no doubt that exfoliation of the callous tissue can be brought about by preparations of this description if they are used in sufficient quantity to impregnate the growth The chief danger in their use would seem to be injudicious and excessive application, especially where they are not confined strictly to the growth They do not, as a rule, separate the more organised apex of the chronic corn

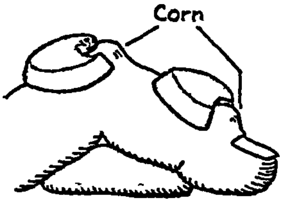
Another popular remedy is the corn ring made of felt spread with isinglass or the more tenacious zinc oxide or rubber adhesive The corn-ring often acts successfully as a temporary remedy, but, since it compresses the growth on all sides, is apt eventually to concentrate the centre of the growth so as to make it more painful than before This is less likely to occur when the anterior portion of the ring is thinned, leaving the proximal half as the protection In some forms the ring plaster has a salicylic disc placed in the cavity to cover the corn, this has the advantage of localising the action of the acid

Operative Methods

The foot or toe should be properly cleansed and then painted well with tinct iodi mitis, which does not necessarily obscure the working; alternatively lint saturated with a 1 in 20 or 1 in 40 aqueous solution of carbolic acid may be applied in close contact with the field of operation for at least five minutes before working The last-named procedure is useful as it tends to lessen surface sensibility

Some chiropodists practise removing the corn in its entirety by the use of mouse-tooth forceps and scalpel, but this method is not very popular in Great Britain, where the general practice is to pare away the surface and excavate the corn even to its minute nucleus, this cannot always be managed at one operation, but it can be mostly done by the skilled manipulator who pays particular attention to making tense the soft tissues with the fingers of his left hand so that there is no impingement or drag on the surrounding sensitive tissue Lightness of touch is essential

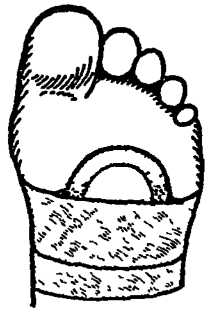
Fig 1



Showing pads and prop in position

(The figures are from "Practical Chiropody," The Scientific Press, Ltd)

Fig 2.



Showing centre pad in position and the metatarsal strapping used to correct lateral spread

After the complete enucleation of the corn the operator gives his attention to restoring the tissue to its normal condition Here two essentials must be observed, first, any semblance of a bursal sac must be enucleated, and the papillæ must be induced to resume their normal form The latter condition may be brought about by the use of a nitrate of silver solution (25 per cent), by compound tincture of benzoin or balsam of Peru Another essential is the removal of the cause of the trouble Corns usually form upon the prominences of the foot more directly in contact with the shoe As a rule this is due to malalignment with flexion of the toes, which often is accompanied by lateral spread and possibly misplacement of the metatarsal bones It is quite possible, where the ligaments and tendons of the toes will allow them to be straightened, to correct this spread by judicious padding A carefully adapted prop placed underneath the toe so as slightly to lift the distal and second phalanges, with a crescent-shaped pad placed on the dorsi proximal aspect (see Fig 1), will often have a straightening effect as well as providing protection to a flexed toe It is hardly necessary to point out that unless this padding is done skilfully it may damage rather than help the condition, but in many cases where feet have spread laterally a carefully adjusted strap round the metatarsal bones has been beneficial in restoring alignment (Fig 2)

Radical excision of the growth has been successfully performed by surgeons, but following this operation there have been occasional cases when minute corns have formed on the cicatrix, which have caused pain as intense as that produced by the original growth

Seed-Corns

A peculiar type of corn which is often found in persons with very dry skins consists of small nuclei about the size of a millet seed These corns are usually multiple and may be distributed more or less uniformly over any part of the plantar surface of the foot They occur virtually irrespective of pressure and are found especially in people of mature age Sometimes small crystalline bodies may be found involved in the nuclei The heel and plantar arch are often the principal seat of this particular trouble These growths can be picked out individually, but the use of a mild salicylic plaster (5 per cent) covering the whole area for three or four days prior to operation greatly facilitates removal

Verrucæ

A type of growth which has something in common with, and is often mistaken for, an ordinary corn is a pathological condition of the prickle-cell layer known as verrucæ These pedic warts are most commonly found in growing children, but I have noticed that during and since the war many more adults have been subject to this trouble which, on the foot, is a source of great pain These warts are infectious, but I have found that the successful cure of one attack of verrucæ of the foot produces immunity from others for many years, if not permanently Trauma is one of the factors in producing these formations, they mostly grow on the fleshy parts of the foot, such as the plantar surface of the metatarso-phalangeal region and on the same area of the heel, but they may occur in other parts of the foot and are occasionally met with on the dorsum of the joints in the usual position of ordinary corns, at the apex of the toes, or even under the edges of the nails When the surface is cleared away by paring there is disclosed a spongy growth which shows the ends of elongated papillæ combined with soft cells As a consequence of the rapid proliferation of the cells of the rete Malpighii the papillæ are so crowded by this accumulation that they become attenuated and squeezed upward and downward, their capillaries being often obliterated, though not always, since, when the growth is pared, there may be slight hæmorrhage from its centre The sponge-like surface may be dotted here and there with small dark-red or blackish stains, and the growth has a rubber-like consistency There is usually a history of throbbing pain, especially on lowering the foot to the ground after a night's rest, on putting on a boot in the morning, and on immersion of the foot in hot water After the boot has been worn for some time the pain may get better Surgeons treat these cases by excision, radium, or X rays Chiropodists sometimes apply the minor forms of electricity if trained in its use, most of them use chemical escharotics such as nitric, monochloracetic, trichloracetic, pyrogallic, chromic, or salicylic acids When treating these cases the chiropodist makes a point of using removable pads judiciously adjusted in order to obviate any direct pressure

ADOLESCENT ALBUMINURIA

To the Editor of THE LANCET.

SIR,—Dr. H. H. Bashford's article in your last week's issue raises several interesting points and it supports the current medical teaching as to the significance of adolescent albuminuria as illustrated by patients whom he has observed for 7 to 14 years. The condition under discussion is that of albuminuria occurring in young adults unaccompanied by any other signs of renal or constitutional disability. I would emphasise the importance of Dr. Bashford's opinion that "those cases in which albumin is consistently found in the after-rest specimen ought certainly to be regarded more stringently" than those in which the after-rest specimen is albumin-free. The opinion, thus expressed, is more conservative than is the statement in his fourth conclusion, "That in the great majority of cases the after-rest specimen is usually free from albumin."

I believe that the presence of albumin in the after-rest specimen distinguishes certain cases which might otherwise be diagnosed as suffering from adolescent or functional albuminuria; and I believe that in some of these cases the albuminuria is an expression of irritation of the renal parenchyma by bacterial toxins. They come properly, therefore, under the heading of toxæmic kidney. I think that I have seen albuminuria as the sole expression of abdominal tuberculous adenitis, and I believe that focal sepsis, such as occurs in chronic tonsillitis is responsible for albuminuria in others. In these patients there has been a trace or faint trace of albumin in the after-rest specimen, but no cells or casts or other evidence in the present condition or past history to indicate renal or constitutional disability. These cases occupy an intermediate position clinically between functional albuminuria and Bright's disease.

I am, Sir, yours faithfully,

GEOFFREY EVANS.

Park-square East, London, N.W., Dec 27th, 1926.

THE INCUBATION PERIOD OF TUBERCULOSIS

To the Editor of THE LANCET.

SIR,—We have in Plymouth a residential hostel for children, who are "contacts" in tuberculous families but are apparently healthy. The evidence afforded by the 20 years work in France of Grancher, and more recently of Leon Bernard, Calmette, and others confirms my own experience, as tuberculosis officer in Plymouth of the frequency of "personal" infection. Under our national system of tuberculosis schemes we have a regular examination of all "contacts" and it is difficult to understand why public health committees do not more often permit tuberculosis officers to send selected cases to such hostels or to board them out thus minimising the risk of infection of the coming generation which arises from intimate association with "open" or advanced tuberculosis in overcrowded premises. My immediate object in writing is to obtain if possible reliable statistics of the incubation period or periods of pulmonary and *other forms* of tuberculosis in man and animals. The periods may vary, as far as my notes of cases show, with the type of tuberculosis with the organs, systems, or structures involved (e.g., a few weeks in the meninges, many months or years in the lungs and the joints), and with age and sex. Such variability in the periods between primary infection and clinical manifestation is, of course common to many *bacterial diseases*, such as leprosy. I should be content with obtaining approximate statistics which may assist those who are attempting to educate the public in this important preventive measure.

I am, Sir, yours faithfully,

F. G. BUSHNELL, M.D., C.C.

Plymouth, Dec 24th, 1926.

PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—The recent correspondence under this heading in your columns did not exhaust the question of the effect of heat upon milk, to which I should like to return. Various speakers at the National Milk Conference held in November last seemed to think that clean milk from tested herds must necessarily be an expensive article, and that all milk that was not produced from tubercle-free herds must be pasteurised. If these assumptions are true, then it necessarily follows that the milk-supply in our large centres of population will be reduced to the position of those found in New York—namely, 2 per cent. of the supply is Certified Milk sold at a price which makes it a fancy article and 98 per cent. is pasteurised. In England, on the other hand, it is possible to sell Grade A (tuberculin-tested) milk in our provincial towns at a price which is not more than *1d.* a quart higher than that of ordinary milk, and in the poorest parts of London at a price which is not more than *2d.* a quart above the price of ordinary milk.

There remains the question, whether or not it is advisable that the people of this country shall admit that the pasteurisation of milk is the true remedy for the difficulties of the milk industry, as was constantly suggested at the conference, or whether, as a nation, we should not press forward to the true goal—namely, the provision of a fresh, clean milk free from disease, at a price which the consumer can pay. Such a policy is undoubtedly in the best interests of the farmers. It is also in the best interests of the consumers. The answer to this question is closely linked up with that of the true food value of fresh and heated milk.

A study of the work that has been carried out in recent years reveals certain facts which should be given grave consideration before a policy, from which it will be very difficult to retire is adopted. In considering this work it is important to remember that many of the problems connected with milk as the ideal food are complicated by the fact that no two human frames react equally: thus in the experiments on the vitamins one is faced by the fact that vitamins are stored in the body, and the number of months a child will flourish on that store will vary within a wide range. The difficulty, therefore, in assessing the true value of vitamins in milk and the amount of destruction by heat can be appreciated. That there is a danger of widespread pasteurisation affecting the health of children cannot be denied after reading Dr. E. A. Barton's paper in the *Journal of State Medicine* (1922) or the article by Prof. E. Widmark in THE LANCET of 1924, i., 1206. The latter drew attention to the widespread outbreak of xerophthalmia that occurred in Denmark owing to the excessive export of butter that took place from economic causes during and after the Great War. J. H. Hess in his work on "Scurvy Past and Present" shows that definite outbreaks of scurvy occurred in Berlin in 1901, when large pasteurisation plants were established, and again when homogenised milk came into use in Switzerland and France.

As Barton pointed out the diminished supply of vitamin from pasteurised milk can be made good by outside factors—e.g., fruit, cod-liver oil, &c.—but unfortunately all mothers have not the means or the opportunity thus to supplement their children's diet. In any event there is no evidence that these additions replace the alterations in the relationship between diffusible and non-diffusible lime salts which takes place on the heating of milk. Much valuable work is now being done on this question. Its importance to the growing child must not be overlooked as it may have an appreciable effect upon the satisfactory formation of the bones and upon the calcium content of the blood. H. E. Magee and Harvey, of the Rowett Research Institute, have shown that the calcium in milk is in two forms, one soluble or ionised and the other organically bound up with caseinogen in the form of a protein salt. They further show that chief danger in their use would seem to be injudicious and excessive application, especially where they are not confined strictly to the growth They do not, as a rule, separate the more organised apex of the chronic corn

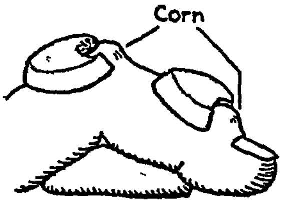
Another popular remedy is the corn ring made of felt spread with isinglass or the more tenacious zinc oxide or rubber adhesive The corn-ring often acts successfully as a temporary remedy, but, since it compresses the growth on all sides, is apt eventually to concentrate the centre of the growth so as to make it more painful than before This is less likely to occur when the anterior portion of the ring is thinned, leaving the proximal half as the protection In some forms the ring plaster has a salicylic disc placed in the cavity to cover the corn ; this has the advantage of localising the action of the acid

Operative Methods

The foot or toe should be properly cleansed and then painted well with tinct iodi mitis, which does not necessarily obscure the working; alternatively lint saturated with a 1 in 20 or 1 in 40 aqueous solution of carbolic acid may be applied in close contact with *the field of operation for at least five minutes* before working The last-named procedure is useful as it tends to lessen surface sensibility

Some chiropodists practise removing the corn in its entirety by the use of mouse-tooth forceps and scalpel, but this method is not very popular in Great Britain, where the general practice is to pare away the surface and excavate the corn even to its minute nucleus, this cannot always be managed at one operation, but it can be mostly done by the skilled manipulator who pays particular attention to making tense the soft tissues with the fingers of his left hand so that there is no impingement or drag on the surrounding sensitive tissue Lightness of touch is essential

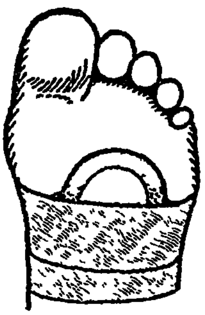
FIG 1



Showing pads and prop in position

(The figures are from "Practical Chiropody," The Scientific Press, Ltd)

FIG 2



Showing centre pad in position and the metatarsal strapping used to correct lateral spread

After the complete enucleation of the corn the operator gives his attention to restoring the tissue to its normal condition Here two essentials must be observed, first, any semblance of a bursal sac must be enucleated, and the papillæ must be induced to resume their normal form The latter condition may be brought about by the use of a nitrate of silver solution (25 per cent), by compound tincture of benzoin or balsam of Peru Another essential is the removal of the cause of the trouble Corns usually form upon the prominences of the foot more directly in contact with the shoe *As a rule* this is due to malalignment with flexion of the toes, which often is accompanied by lateral spread and possibly misplacement of the metatarsal bones It is quite possible, where the ligaments and tendons of the *toes* will allow them to be straightened, to correct this spread by judicious padding A carefully adapted prop placed underneath the toe so as slightly to lift the distal and second phalanges, with a crescent-shaped pad placed *on* the dorsi proximal aspect (see Fig 1), will often have a straightening effect as well as providing protection to a flexed toe It is hardly necessary to point out that unless this padding is done skilfully it may damage rather than help the condition, but in many cases where feet have spread laterally a carefully adjusted strap round the metatarsal bones has been beneficial in *restoring* alignment (Fig 2)

Radical excision of the growth has been successfully performed by surgeons, but following this operation there have been occasional cases when minute corns have formed on the cicatrix, which have caused pain as intense as that produced by the original growth.

Seed-Corns

A peculiar type of corn which is often found in persons with very dry skins consists of small nuclei about the size of a millet seed. These corns are usually multiple and may be distributed more or less uniformly over any part of the plantar surface of the foot They occur virtually irrespective of pressure and are *found especially* in people of mature age Sometimes small crystalline bodies may be found involved in the nuclei The heel and plantar arch are often the principal seat of this particular trouble These growths can be picked out individually, but the use of a mild salicylic plaster (5 per cent) covering the whole area for three or four days prior to operation greatly facilitates removal

"Audi alteram partem"

ADOLESCENT ALBUMINURIA

To the Editor of THE LANCET

SIR,—Dr. H. H. Bashford's article in your last week's issue raises several interesting points, and it supports the current medical teaching as to the significance of adolescent albuminuria as illustrated by patients whom he has observed for 7 to 14 years. The condition under discussion is that of albuminuria occurring in young adults unaccompanied by any other signs of renal or constitutional disability. I would emphasise the importance of Dr. Bashford's opinion that "those cases in which albumin is consistently found in the after-rest specimen ought certainly to be regarded more stringently" than those in which the after-rest specimen is albumin-free. The opinion, thus expressed, is more conservative than is the statement in his fourth conclusion, "That in the great majority of cases the after-rest specimen is usually free from albumin."

I believe that the presence of albumin in the after-rest specimen distinguishes certain cases which might otherwise be diagnosed as suffering from adolescent or functional albuminuria; and I believe that in some of these cases the albuminuria is an expression of irritation of the renal parenchyma by bacterial toxins. They come properly, therefore, under the heading of toxæmic kidney. I think that I have seen albuminuria as the sole expression of abdominal tuberculous adenitis, and I believe that focal sepsis, such as occurs in chronic tonsillitis, is responsible for albuminuria in others. In these patients there has been a trace or faint trace of albumin in the after-rest specimen, but no cells or casts or other evidence in the present condition or past history to indicate renal or constitutional disability. These cases occupy an intermediate position clinically between functional albuminuria and Bright's disease.

I am, Sir, yours faithfully,

GEOFFREY EVANS.

Park square East, London, N.W., Dec. 27th, 1926.

THE INCUBATION PERIOD OF TUBERCULOSIS

To the Editor of THE LANCET

SIR,—We have in Plymouth a residential hostel for children, who are "contacts" in tuberculous families but are apparently healthy. The evidence afforded by the 20 years' work in France of Grancher, and more recently of Léon Bernard, Calmette, and others, confirms my own experience, as tuberculosis officer in Plymouth, of the frequency of "personal" infection. Under our national system of tuberculosis schemes we have a regular examination of all "contacts," and it is difficult to understand why public health committees do not more often permit tuberculosis officers to send selected cases to such hostels or to board them out, thus minimising the risk of infection of the coming generation which arises from intimate association with "open" or advanced tuberculosis in overcrowded premises. My immediate object in writing is to obtain, if possible, reliable statistics of the incubation period or periods of pulmonary and other forms of tuberculosis in man and animals. The periods may vary, as far as my notes of cases show, with the type of tuberculosis with the organs, systems, or structures involved (e.g., a few weeks in the meninges, many months or years in the lungs and the joints), and with age and sex. Such variability in the periods between primary infection and clinical manifestation is, of course, common to many bacterial diseases, such as leprosy. I should be content with obtaining approximate statistics which may assist those who are attempting to educate the public in this important preventive measure. I am, Sir, yours faithfully,

F. G. BUSHNELL, M.D., C.C.

Plymouth, Dec. 24th, 1926.

PASTEURISATION OF MILK

To the Editor of THE LANCET

SIR,—The recent correspondence under this heading in your columns did not exhaust the question of the effect of heat upon milk, to which I should like to return. Various speakers at the National Milk Conference held in November last seemed to think that clean milk from tested herds must necessarily be an expensive article and that all milk that was not produced from tubercle-free herds must be pasteurised. If these assumptions are true, then it necessarily follows that the milk-supply in our large centres of population will be reduced to the position of those found in New York—namely, 2 per cent. of the supply is Certified Milk sold at a price which makes it a fancy article and 98 per cent. is pasteurised. In England, on the other hand, it is possible to sell Grade A (tuberculin-tested) milk in our provincial towns at a price which is not more than 1*d.* a quart higher than that of ordinary milk, and in the poorest parts of London at a price which is not more than 2*d.* a quart above the price of ordinary milk.

There remains the question, whether or not it is advisable that the people of this country shall admit that the pasteurisation of milk is the true remedy for the difficulties of the milk industry, as was constantly suggested at the conference, or whether, as a nation, we should not press forward to the true goal—namely, the provision of a fresh, clean milk free from disease, at a price which the consumer can pay. Such a policy is undoubtedly in the best interests of the farmers. It is also in the best interests of the consumers. The answer to this question is closely linked up with that of the true food value of fresh and heated milk.

A study of the work that has been carried out in recent years reveals certain facts which should be given grave consideration before a policy, from which it will be very difficult to retire is adopted. In considering this work it is important to remember that many of the problems connected with milk as the ideal food are complicated by the fact that no two human frames react equally; thus, in the experiments on the vitamins one is faced by the fact that vitamins are stored in the body, and the number of months a child will flourish on that store will vary within a wide range. The difficulty, therefore, in assessing the true value of vitamins in milk and the amount of destruction by heat can be appreciated. That there is a danger of widespread pasteurisation affecting the health of children cannot be denied after reading Dr. E. A. Barton's paper in the *Journal of State Medicine* (1922) or the article by Prof. E. Widmark in THE LANCET of 1924, i., 1206. The latter drew attention to the widespread outbreak of xerophthalmia that occurred in Denmark owing to the excessive export of butter that took place from economic causes during and after the Great War. J. H. Hess in his work on "Scurvy Past and Present" shows that definite outbreaks of scurvy occurred in Berlin in 1901, when large pasteurisation plants were established, and again when homogenised milk came into use in Switzerland and France.

As Barton pointed out, the diminished supply of vitamin from pasteurised milk can be made good by outside factors—e.g., fruit, cod-liver oil, &c.—but unfortunately all mothers have not the means or the opportunity thus to supplement their children's diet. In any event there is no evidence that these additions replace the alterations in the relationship between diffusible and non-diffusible lime salts which takes place on the heating of milk. Much valuable work is now being done on this question. Its importance to the growing child must not be overlooked, as it may have an appreciable effect upon the satisfactory formation of the bones, and upon the calcium content of the blood. H. E. Magee and Harvey, of the Rowett Research Institute, have shown that the calcium in milk is in two forms, one soluble or ionised, and the other organically bound up with caseinogen in the form of a protein salt. They further show that the percentage of diffusible CaO present in fresh milk is 26.1 per cent., in pasteurised milk (i.e., milk held at 70° C. for 30 minutes) is 20.4 per cent., and in boiled milk (i.e. a flask of milk immersed in a water-bath at boiling-point for one hour) is 15.7 per cent.

Dr. A. T. R. Mattick has kindly permitted me to make use of as yet unpublished details of work which is being carried out on the effect of heat on the diffusible calcium of milk. A long series of experiments has been carried out at temperatures which ranged from 105° to 210° F. In each experiment the milk was held at a temperature which did not vary more than 5 degrees. In every case the amount of diffusible calcium was diminished and the coagulation time of the heated milk when treated with rennet was prolonged as the temperature rose, until at a temperature of 205° to 209° F. no true coagulation took place. In New York an investigation by W. S. Ladd, Ewarts, and Franks on the relative efficiency of Certified and pasteurised milk for infant feeding was made. It was found that Certified raw milk alone without the addition of orange-juice or cod-liver oil produced a greater increase of body-weight in babies than did pasteurised milk alone or when pasteurised milk was combined with orange-juice and cod-liver oil. The table is as follows:—

—	No. of months observed	Weight development— At entrance	Weight development— At one year	Weight development— Gain in percentage
		Per cent.	Per cent.	Per cent.
Group I. (61 cases) Grade A pasteurised Cod liver oil 0 Orange juice 0	6.9	82.1	83.8	1.7
Group II. (59 cases) Grade A pasteurised Cod liver oil 0 Orange juice +	7.2	82.2	90.1	7.9
Group III. (72 cases) Grade A pasteurised Cod liver oil + Orange juice +	7.0	80.2	89.7	9.5
Group IV. (17 cases) Certified milk, raw Cod liver oil 0 Orange juice 0	6.8	80.0	94.0	14.0

This table shows that the normal development of the babies as judged by weight increased 14 per cent. on Certified raw milk against 1.7 per cent. on pasteurised milk alone, 7.9 per cent. on pasteurised milk with the addition of orange-juice, and 9.5 per cent. on pasteurised milk with the addition of orange-juice and cod-liver oil. A. L. Daniels and G. Stearns, of the Iowa Child Welfare Research Centre, found that in experiments on rats, that when the rats were fed on pasteurised milk their growth was half the normal. According to them this was due to the precipitation of calcium, the calcium adhering to the sides of the vessel in which the milk was pasteurised. If, however, the vessel was washed after the milk had been poured out, and the washings added to the milk, then the growth of the rats was normal. In the Iowa Welfare Centre it was found that babies fed on pasteurised milk (milk held at 145° F. for 30 minutes) did not increase in weight. This was found to be again due to the loss of diffusible calcium in the pasteurised milk. This was proved by the fact that the stools of the babies fed on pasteurised milk contained more total calcium than those fed on milk that had been heated to 145° F. and then immediately cooled.

From the above few observations it may be acknowledged that the pasteurisation of milk is not ideal and that the indiscriminate use of pasteurised milk by the great majority of the population is not to be recommended.

I am, Sir, yours faithfully,
C. MADDOCK, C.I.E., M.D.,
Lieut.-Col. I.M.S. (ret.), Hon. Sec., Grade A (Tuberculin Tested) Milk Producers' Association.

THE PRACTICE OF PATHOLOGY

To the Editor of THE LANCET.

SIR,—May we draw attention to the fact that a meeting will be held at the London School of Medicine for Women at 2.30 P.M. on Friday, Jan. 7th, for the purpose of considering the advisability of forming a society to represent the interests of those engaged in the practice of pathology?

There is general agreement among those engaged therein that the conditions of pathological practice throughout the country are very unsatisfactory, and are in danger of becoming more so. The competition for pathological work on the part of subsidised institutions of various sorts, both academic and commercial, and of local authorities, and the resultant cutting of fees, is threatening to reduce the remuneration from pathological work to such an extent that little inducement will be offered to competent men to enter this important branch of medical practice. The present state of pathological practice, moreover, offers little encouragement to non-teaching hospitals to attempt to bring their pathological departments to a state of efficiency. It is in the general interest of medicine that pathological knowledge should be as widespread as possible, and not confined to the teaching centres.

Up to the present pathologists as a class have had no organisation to represent their interests. The need for such a body appears to be urgent, and we, therefore, hope that all those interested who can manage to do so will attend the meeting.

We are, Sir, yours faithfully,
H. A. COOKSON,
Royal Infirmary, Sunderland.
J. B. DAVEY,
General Hospital, Cheltenham.

MEDICINE OR SURGERY FOR THE OCULIST?

To the Editor of THE LANCET.

SIR,—"Incipiens," in his letter of Dec. 4th, has taken the wrong point of view. It is not a question of what form of education would be best for an oculist or best for ophthalmology, but what form of test shall be applied to reduce the number of would-be oculists.

It is useless to argue that a medical education is more suitable for an oculist than a purely surgical one, or that the ophthalmic problems awaiting solution are mainly medical. The hospital appointments are few, and it is obvious that some test must be introduced to keep the numbers of applicants within bounds. The attempt to settle the question on the merits and attainments of the applicants would be much too onerous a labour for any medical committee. For it matters not what the applicant's ophthalmic qualifications may be, if he have not the Fellowship the merest tyro in ophthalmology with the Fellowship will get the appointment before him.

The tragedy is that men are encouraged to take up ophthalmology in order to obtain their services as clinical assistants and house surgeons, and then, no matter what their attainments, their further progress is debarred, not by an examination in ophthalmology but by a purely surgical examination Surely it is time that the whole question of hospital appointments, not only in ophthalmic hospitals, but in other specialties, should be reconsidered. The distinction between medicine and surgery in any specialty is artificial and detrimental to its best interests but to debar men of proved ability by an examination test is the height of injustice

The insistence on the Fellowship as an essential to an ophthalmic post is injurious to ophthalmology, and deprives London of some of the best men

I am, Sir, yours faithfully,

Dec 20th, 1926 Respiciens

LOSS OF MEMORY

To the Editor of The Lancet.

Sir,—In your leading article of Dec 25th, 1926, you refer to Dickens's story of Dr Manette It is of interest to note that Spinoza (whose anticipation of modern psychological theories is, in many instances, remarkable) relates the case of a Spanish poet who as the result of an illness, suffered from what we should term a dissociation of personality ("Ethica," Part IV, Prop 39, Scholium) It seems probable that such a dissociation of personality, due to a break in the continuity of consciousness may be the cause of the change of character which so often follows an attack of encephalitis lethargica

I am, Sir, yours faithfully,

Birmingham, Dec 27th, 1926 M Hamblin Smith.

TUBERCULOSIS OF THE KIDNEY

To the Editor of The Lancet

Sir,—With reference to the article by Mr White and your leading article on the same subject, I think it is important to point out (1) that operation is not necessary to make a diagnosis of hidden tuberculosis of the kidney, such cases can be diagnosed quite easily by tuberculin reactions and cured with tuberculin alone, (2) when the disease is open there is nearly always a mixed infection and it is absolutely essential to treat this with an autogenous antigen If I am not mistaken as to the case referred to by Mr Pringle and Sir W Taylor, he had both a *B coli* and a *Staphylococcus aureus* infection for which a mixed antigen was used

In my experience it is only rarely that these cases call for surgical interference—e g if there is a perirenal abscess which must be drained or when in a unilateral case the kidney has become completely disorganised With our present resources of diagnosis and treatment such cases should not occur

I am, Sir, yours faithfully,

W M Crofton

Donations and Bequests —Under the will of the late Miss Fanny Sarah Longman, of Cliveden-terrace, Eaton-square, S W, the testatrix left £1000 each to the Chelsea Hospital for Women, the Disabled Soldiers' Hospital, Richmond, the National Institute for the Blind St. Dunstan's Hostel, the British Red Cross Society, the Hospital Sunday Fund and the Church Army, £300 to Dr Barnardo's Homes £200 each to the Infant Asylum, Wanstead, the Royal London Ophthalmic Hospital the Great Ormond street Hospital for Children the School for the Indigent Blind Leatherhead the Church of England Waifs and Strays Society, Queen Charlotte s Hospital Marylebone road, the Cripples' Home, Marylebone-road the Hospital for Women Soho, the National Lifeboat Institution, the Royal Hospital for Incurables, Putney, St Giles' Christian Mission, the Earlswood Asylum the Royal Albert Orphan Asylum, the Cancer Hospital Fulham, the Hospital for Consumption Brompton, the Hostel of God—Free House for Dying, Clapham Common, the City of London and West London Dispensary, the Miller Hospital, Greenwich the Royal Asylum of St Anne's Society, the Society for the Prevention of Cruelty to Animals, and the London City Mission

Obituary.

JOSEPH EBENEZER ADAMS, M S Lond, F R C S Eng

The death of Mr Joseph Adams on Dec 21st removes a London surgeon whose qualities were justly respected He gave loyal service to St Thomas s Hospital and to the East London Hospital for Children and his premature death will be generally regretted by those who worked with him

Mr J E Adams

Born in 1878, Joseph Adams was the fifth son of William Adams who was a City merchant He was educated at the City of London School, and won a scholarship at St Thomas's Hospital, where he soon made his mark as a student He qualified in 1902 and became a Fellow of the Royal College of Surgeons a couple of years later From 1905 until 1909 he held the post of surgical registrar and resident assistant surgeon at St Thomas's Hospital and soon afterwards he was elected surgeon to the East London Hospital for Children Shadwell, at the time of his death Mr Adams was senior surgeon to this institution, in which he took a great interest In 1913 he was appointed assistant surgeon to St Thomas's Hospital and in the same year delivered a Hunterian lecture [1] on peritoneal adhesions, to the Royal College of Surgeons This described some of the experimental work which he had already begun and which was to continue until his death Most of his research was devoted to abdominal conditions and it always showed the thoroughness and attention to detail which were characteristic of him Not long before the war in collaboration with Dr M A Cassidy, he wrote a book on acute abdominal diseases, and this he subsequently revised and enlarged, so that it became a valuable text-book for students A second Hunterian lecture given at the Royal College of Surgeons last year, continued further results of his investigations of the abdomen and dealt with the surgery of the jejunum He was interested, however, in many other branches of surgery, and will be remembered for his advocacy of wider education of the public concerning the nature and control of cancer He did not feel certain that the medical profession was doing all that might be expected to combat the disease. "Personally," he once said, "I would rather spend my time reassuring patients who have not got cancer than operating on those who have," and he thought that more money should be spent on propaganda, "so that the sick person shall no longer attribute to the hand of God what is probably due to the carelessness of man."[2] He was often to be seen at meetings of the Association of Surgeons, of which he was an original member, and of the surgical and other sections of the Royal Society of Medicine. His opinions were always given clearly, concisely, and to the point—whether at meetings of societies or in his contributions to medical journals. The same care and deliberation were apparent in his operative work as in his writing, for they were a part of his personality. He was enthusiastic about teaching at St Thomas's, and his own clear thinking allowed him to present his subject in a logical manner. His qualities as a man were obvious. "Adams never shirked his hospital work," writes a colleague. "He was a man of character with high ideals and he considered that the training of his house surgeons and his dressers was a duty not to be lightly undertaken. . . All through his life absolute straight dealing and integrity were the dominating features of his character. In the early days when he was resident assistant surgeon he was looked up to and trusted by College House. It would have been impossible for Adams to do a mean or crooked action. He was generous both in his thoughts and actions, a characteristic which was never paraded, for, being a sensitive and reserved man, he sometimes cloaked his real feelings under a veil of sarcasm. His tragic death at the early age of 48 is a real loss to the profession, to the hospitals at which he worked, and to his friends."

---

[1] The Lancet, 1913, i, 663

Mr Adams often carried on his work under considerable physical disability which proved due to a congenital diaphragmatic hernia. Symptoms arose from it which prevented his serving overseas during the late war, and he is said to have felt the restriction keenly. As a student he played cricket for St Thomas's, and later he took up golf, but in the latter part of his life his favourite recreation was to visit his cottage at Penshurst, where he gardened enthusiastically, and nothing gave him greater pleasure than to get his friends and his students to go with him. Mr Adams married, in 1913, Muriel, youngest daughter of the late Mr Harry Webb, of Chislehurst, and she survives him.

THOMAS S PIGG STRANGEWAYS,

M A CAMB, M R C S ENG

WE have to record that Dr T S P Strangeways died on Dec 23rd at Cambridge, where he was lecturer on special pathology in the University. Originally named Strangeways Pigg, he received his medical education at St Bartholomew's Hospital in the early nineties of last century. Even as a student he suffered from a degree of deafness which would have deterred most men from attempting a medical career, and this disability, together with his retiring character, was doubtless the reason why he attracted little notice as a student. He gained, however, one hospital distinction—namely, the Matthews Duncan gold medal in obstetrics—which was awarded to him in 1896. In the same year he took the examination of the Conjoint Board, never having aimed at a University degree. It was probably the most fortunate circumstance in his life that just at this period he came under the influence of A A Kanthack, then recently appointed lecturer on pathology at St Bartholomew's. Kanthack had a good eye for ability, and he recognised in this quiet and unassuming student capacities which had escaped the notice of others—a notable keenness and a great power for hard work. Strangeways was made junior curator of the museum at the hospital, and worked under Kanthack until early in 1897, when the latter was called to the chair of pathology at Cambridge. Not many months had elapsed before Strangeways followed Kanthack to the University to act as his demonstrator. The time that followed was the happiest period of his life. He could never have succeeded in general practice owing to his deafness, but this affliction was little bar to teaching and none to research. He settled down in Cambridge to a steady career of teaching and laboratory work in which his abilities found full scope, and he soon became a well-established figure in the Cambridge Medical School. At the beginning of this century pathology was not yet divided up into the several compartments which we see to-day. Strangeways taught morbid anatomy and histology, bacteriology, and clinical pathology. He was an excellent and popular teacher, in spite of a certain brusqueness of manner; he got to know his men and he remembered them in after life; they responded by developing a real affection for him. For the use of his classes he prepared a small laboratory handbook which ran through seven editions. When the Cambridge Research Hospital was founded, largely through his own efforts, Strangeways naturally became its director, and carried on his extensive research without any material cessation of his teaching work. The subject chosen for investigation at the new hospital was chronic arthritis, and into its study Strangeways threw himself for many years with eager enthusiasm. It was hoped that the intensive scientific examination of this confused and protean condition would lead to the solution of some at least of the many problems of its causation and treatment. Strangeways and his colleagues did indeed learn much of the disease and arrived at a certain classification; they summarised their conclusions in a series of 48 categorical statements,[3] but it was certainly a disappointment that the great amount of labour devoted to the subject did not prove more fruitful.

DR STRANGEWAYS

For the last few years of his life Strangeways turned to a new study—the study of tissue culture. Here he attained results commensurate with his efforts, and became perhaps the leading exponent in this country of the delicate technique required; those who saw the preparations—illustrating the development of the limb bud and of the eye in vitro—shown during the past two years at the Royal Society, realised what a master of the art he had become. During these last years he had collected around him five whole-time workers at Cambridge and was associated also with a team of workers at St Bartholomew's Hospital who were engaged in the study of the action of radium and X rays on living cells, for which he provided all the tissue cultures needed. The fruits of this combined research have been in part published, but much remains to be done.

Strangeways died in harness, going straight from the laboratory to his last sickbed. By a curious irony the last lecture which he ever delivered was on Death and Immortality, and he illustrated it by a preparation bearing marvellous witness to his technical skill—a living culture of tissue made from a sausage purchased in the town.

During the late war he acted for the War Office as Government inspector of pathological laboratories. He married a daughter of the late Edward Anthony Beck, master of Trinity Hall, Cambridge, and leaves his widow with seven children.

TUESDAY Jan 4th —3 15 P M , Mr L E Barrington Ward Gall stones

POST GRADUATE HOSTEL, Imperial Hotel, Russell square, W C

TUESDAY Jan 4th —9 P M , Dr C E Goddard Lord Lister, by one who knew him

THURSDAY —Mr Philip Turner *Imperfect Descent of the Testis* might be expected to combat the disease "Personally," he once said, "I would rather spend my time reassuring patients who have not got cancer than operating on those who have," and he thought that more money should be spent on propaganda, "so that the sick person shall no longer attribute to the hand of God what is probably due to the carelessness of man "[2] He was often to be seen at meetings of the Association of Surgeons, of which he was an original member, and of the surgical and other sections of the Royal Society of Medicine His opinions were always given clearly, concisely, and to the point—whether at meetings of societies or in his contributions to medical journals The same care and deliberation were apparent in his operative work as in his writing, for they were a part of his personality He was enthusiastic about teaching at St Thomas's, and his own clear thinking allowed him to present his subject in a logical manner His qualities as a man were obvious "Adams never shirked his hospital work," writes a colleague "He was a man of character with high ideals and he considered that the training of his house surgeons and his dressers was a duty not to be lightly undertaken . . . All through his life absolute straight dealing and integrity were the dominating features of his character In the early days when he was resident assistant surgeon he was looked up to and trusted by College House It would have been impossible for Adams to do a mean or crooked action He was generous both in his thoughts and actions, a characteristic which was never paraded, for, being a sensitive and reserved man, he sometimes cloaked his real feelings under a veil of sarcasm His tragic death at the early age of 48 is a real loss to the profession, to the hospitals at which he worked, and to his friends"

Mr Adams often carried on his work under considerable physical disability which proved due to a congenital diaphragmatic hernia Symptoms arose from it which prevented his serving overseas during the late war, and he is said to have felt the restriction keenly As a student he played cricket for St Thomas's, and later he took up golf but in the latter part of his life his favourite recreation was to visit his cottage at Penshurst, where he gardened enthusiastically, and nothing gave him greater pleasure than to get his friends and his students to go with him Mr Adams married, in 1913, Muriel, youngest daughter of the late Mr Harry Webb, of Chislehurst, and she survives him

THOMAS S PIGG STRANGEWAYS,

M A Camb, M R C S Eng

We have to record that Dr T S. P Strangeways died on Dec 23rd at Cambridge, where he was lecturer on special pathology in the University Originally named Strangeways Pigg, he received his medical education at St Bartholomew's Hospital in the early nineties of last century Even as a student he suffered from a degree of deafness which would have deterred most men from attempting a medical career, and this disability, together with his retiring character, was doubtless the reason why he attracted little notice as a student He gained, however, one hospital distinction—namely, the Matthews Duncan gold medal in obstetrics—which was awarded to him in 1896 In the same year he took the examination of the Conjoint Board, never having aimed at a University degree It was probably the most fortunate circumstance in his life that just at this period he came under the influence of A A Kanthack, then recently appointed lecturer on pathology at St Bartholomew's Kanthack had a good eye for ability, and he recognised in this quiet and unassuming student capacities which had escaped the notice of others—a notable keenness and a great power for hard work Strangeways was made junior curator of the museum at the hospital, and worked under Kanthack until early in 1897, when the latter was called to the chair of pathology at Cambridge Not many months had elapsed before Strangeways followed Kanthack to the University to act as his demonstrator The time that followed was the happiest period of his life He could never have succeeded in general practice owing to his deafness, but this affliction was little bar to teaching and none to research He settled down in Cambridge to a steady career of teaching and laboratory work in which his abilities found full scope, and he soon became a well-established figure in the Cambridge Medical School At the beginning of this century pathology was not yet divided up into the several compartments which we see to-day Strangeways taught morbid anatomy and histology, bacteriology, and clinical pathology He was an excellent and popular teacher, in spite of a certain brusqueness of manner, he got to know his men and he remembered them in after life, they responded by developing a real affection for him For the use of his classes he prepared a small laboratory handbook which ran through seven editions When the Cambridge Research Hospital was founded, largely through his own efforts, Strangeways naturally became its director, and carried on his extensive research without any material cessation of his teaching work The subject chosen for investigation at the new hospital was chronic arthritis, and into its study Strangeways threw himself for many years with eager enthusiasm It was hoped that the intensive scientific examination of this confused and protean condition would lead to the solution of some at least of the many problems of its causation and treatment Strangeways and his colleagues did indeed learn much of the disease and arrived at a certain classification, they summarised their conclusions in a series of 48 categorical statements,[3] but it was certainly a disappointment that the great amount of labour devoted to the subject did not prove more fruitful

DR STRANGEWAYS

For the last few years of his life Strangeways turned to a new study—the study of tissue culture Here he attained results commensurate with his efforts, and became perhaps the leading exponent in this country of the delicate technique required, those who saw the preparations—illustrating the development of the limb bud and of the eye in vitro—shown during the past two years at the Royal Society, realised what a master of the art he had become During these last years he had collected around him five whole-time workers at Cambridge and was associated also with a team of workers at St Bartholomew's Hospital who were engaged in the study of the action of radium and X rays on living cells, for which he provided all the tissue cultures needed The fruits of this combined research have been in part published, but much remains to be done

Strangeways died in harness, going straight from the laboratory to his last sickbed By a curious irony the last lecture which he ever delivered was on Death and Immortality, and he illustrated it by a preparation bearing marvellous witness to his technical skill—a living culture of tissue made from a sausage purchased in the town

During the late war he acted for the War Office as Government inspector of pathological laboratories He married a daughter of the late Edward Anthony Beck, master of Trinity Hall, Cambridge, and leaves his widow with seven children

[3] The Lancet, 1918, ii, 621

HEALTH AND SICKNESS IN THE NURSERY

ANY book offered to the mothers of the nation by Dame Mary Scharlieb is likely to be gratefully received by them as an aid to the recognition of children's ailments, and an indication of the more elementary forms of nursery treatment The first chapters of Health and Sickness in the Nursery[1] give general information on the characteristics and requirements of infants and small children The rest of the volume consists of an outline of the symptomatology and the elements of treatment of most of the diseases met with in childhood The book may claim to meet the requirements of the mothers of the Empire since plague cholera, and yellow fever are among the nursery complaints described Perhaps the most useful chapter is the one containing an account of the symptoms produced by various common poisons, and their immediate treatment

SWEDISH RACE-HYGIENE

Mr Bernard Shaw recently expressed a wish that the value of the Nobel Prize refused by him should be devoted to the diffusion of knowledge of things Swedish in England The Swedes, however, are perhaps the most self-conscious and best self-advertised among the Nordic nations It is only a few years since two eminent scientific Swedes published an exhaustive account of what in Sweden is termed race-hygiene, a term not yet in use here The full title of the book is "The Swedish Nation in Word and Picture A Jubilee Book given out with the Coöperation of Experts commissioned by the Swedish Society for Race-Hygiene By H Lundborg, M D, Professor, Upsala and J Runnström, D Ph, Lecturer at the University of Stockholm" It was published at Stockholm in 1921, and with its many illustrations of fine Swedish race-types, ranging from nobles and bishops to singularly distinguished-looking peasants it is really a delightful book to peruse and possess It does not, however, appear to have been circulated to any but learned institutions in England, and it was not reviewed in these columns

From the days of the Reformation which took such firm hold of the country that Lutheranism there has often proved a form of clerical fanaticism Sweden has striven by every form of State interference to improve or safeguard an already excellent racial stock. The Gothenburg system an early form of partial Prohibition, need not be more than mentioned, but what is not so well known as it deserves to be is that the Swedish census is the oldest known census in Europe It dates from early in the seventeenth century when it was permissive and in the hands of the all-powerful but well-instructed Lutheran clergy, and so minute and searching is the information it supplies that it is possible to trace with its help the incidence of forgotten epidemics Another old glory of grandmotherly legislation is the royal enactment of date 1734 (in force till 1915), forbidding epileptics to marry The law, it appears, was beneficently stretched to include sufferers from mental and venereal diseases That the law was evaded in remote districts is doubtless true, and these evasions among a wild people would account for the anxiety of legislators to meddle on every occasion with personal liberty and for the emergence of the ill-starred Lister family in the extreme south-west of the country, a large number of whom have been myoclonic epileptics as well as ordinary degenerates and criminals Where the Swedes are in a foreign land, warring or sustaining themselves as a remnant of civilised men among lower races and cultures it becomes impossible to legislate and an appeal only can be made to them. Such an appeal is the fine and rather pathetic document issued by the Society for Improving Public Health in Swedish Finland, which is itself a committee of the Florin Commission, appointed by the Swedish Literary Society in Finland to administer a munificent legacy left them by Miss Jenny Florin in 1911 This lady in her will left 100,000 Fmk to the Literary Society on condition that the interest of the fund should be used to promote medical science The proclamation, issued to the Swedish population of Finland as an illuminated card, contains what cynics might take to be counsels of perfection "On our own will," it begins "on our innate power ultimately depends the future of the Swedish race in our country A people mentally and physically strong can hold out even under hard outward pressure!" You must direct your attention to the children that they are born with a good disposition, that they be well cared for and educated You must be careful to marry only into healthy families, and be on your guard against strong drink and sexual disease "The best inheritance you can give your children is not money and gold but a sound mind in a sound body!" Those who own a piece of ground are adjured not to sell it however much they may be tempted "Rather make it your glory and your pride as your fathers before you to leave it in an improved state to your descendants!" The farmer's life is the healthiest "Do not abandon your native place Above all do not move into town! Teach your children to love truth and keep their word Harden their wills teach them the value of diligence. Briefly all members of our Swedish race should be educated to become honest and diligent workers for their native place and their fatherland! *There must be no bad Swedish men and women in this country!*"

This is a document worthy of the Stoics of old

QUEEN SQUARE

LONDON is changing so fast, and so many old landmarks are daily disappearing in the rage for what is euphemistically called "improvement" that any history of things as they used to be is of value Queen Square which used to consist of beautiful Queen Anne and early Georgian houses, the abode of persons of quality and of a school known by the delightful name of "The Ladies Eton," together with a singularly ugly church described by Maitland in 1756, as "a perfectly plain and most inelegant brick building," has to-day seen the replacement of most of the houses by hospitals and other institutions The church is still there The hospitals include The National Hospital, the Alexandra Hospital, the Italian Hospital, and the Homœopathic Hospital, while the Children's Hospital in Great Ormond-street is not far away It is owing to the love of Mr Heathcote Hamilton Secretary of the National Hospital, for the district in which the hospital is situated that we owe a charming account[1] of the site The new hospitals and institutions have fortunately not swallowed up all the old buildings for Nos 29 to 32 are now the property of the National Hospital and a glance at the excellent photographs of the interior of 29 will show how beautiful an early eighteenth century house could be Mr Hamilton has collected a number of interesting facts about the Square in its early days and its inhabitants At the Ladies Eton, which was kept by Mrs Dennis and her brother Admiral Sir Peter Dennis was educated a child by name Hester Salusbury known to fame afterwards as Mrs Thrale, and Mrs Piozzi who says in a letter circa 1750 how the Admiral "said I was qualified at 8 years old to be teacher rather than learner and he actually did instruct me in the rudiments of navigation as the globes were already familiar to me" Of the gradual change from a purely residential quarter into an institutional one Mr Hamilton's pages give an admirable moving picture

HEALTH CONDITIONS IN CYPRUS

IN the annual report recently issued it is stated that the estimated population of the island at the end of 1925 was about 330,000 The bulk of the inhabitants are of the orthodox Greek-Christian faith Of the remainder some 60,000 are Mohammedans There is also an Armenian community, which tends steadily to increase, and a distinct though not numerous Latin colony Except for the endemic prevalence of malarial fever, the climate of Cyprus is healthy and temperate, and, with proper precautions, there should be no difficulty in enjoying complete immunity from this disease The heat and humidity during the summer months impose a certain strain, but access to the hills is easily practicable within a very short distance The climate during the winter might almost be described as ideal, combining as it does invigorating cold with clear sunshine The continued dullness of more northern climes is seldom experienced, and a rainy day is invariably succeeded by a cloudless sky

Public health in 1925 was again good, and no outbreak of epidemic disease is to be recorded In contrast with all the neighbouring countries of the Levant and the Near East, Cyprus is entirely free from plague, typhus, and other virulent diseases, and stringent quarantine measures are in force against their introduction Phthisis has again demanded and engaged the especial attention of the medical authorities, the number of cases reported being greater than in 1924 Statistics relating to this disease are not, however, wholly to be relied upon, for persons afflicted with it have, in the past, brought considerable pressure to bear to avoid being reported The construction of the Government sanatorium has now been completed, and the new buildings, situated in most healthy surroundings four miles from Nicosia, are ready for the admission of patients As hitherto, the prevailing diseases, other than malaria and phthisis, were those of the digestive and respiratory systems influenza, diseases of the skin, rheumatism, and enteric fever There has been a most noteworthy decrease in the number of cases of enteric fever, following the improvements effected to the water supplies of the towns and villages Cases of trachoma have been on the increase, the numbers having risen from 393 in 1924 to 515 in 1925

Notes, Comments, and Abstracts.

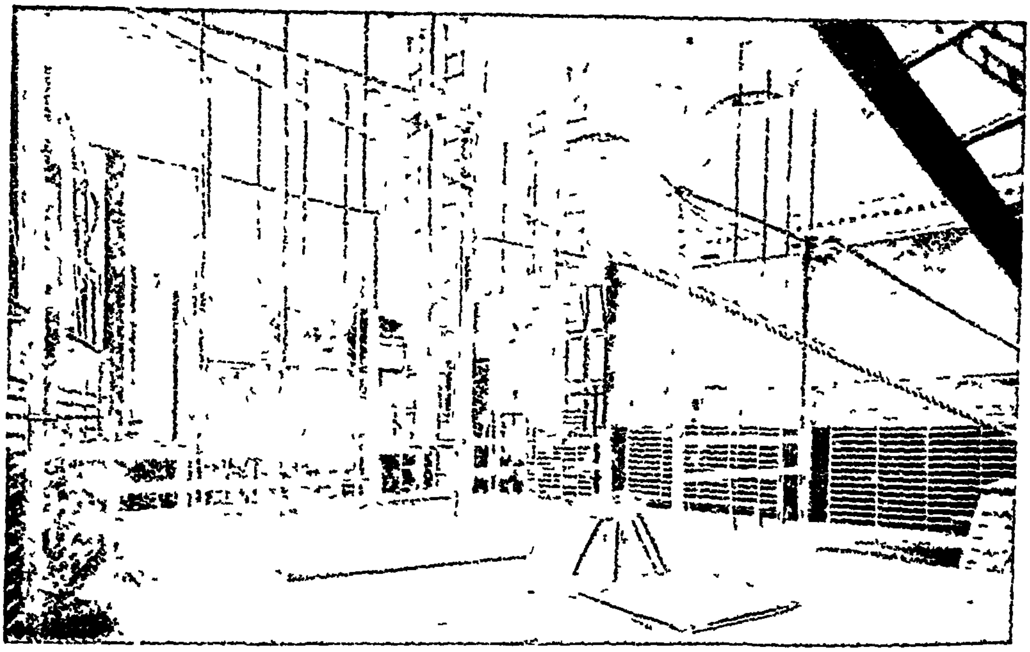
AN INSTITUTE FOR THE PHYSICAL TRAINING OF BOYS

By W H Battle, F R C S Eng ,
CONSULTING SURGEON TO ST THOMAS'S HOSPITAL.

A recent visit to the Lucas-Tooth Institute (St Olave's Institute, Bermondsey) has convinced me that the directors are doing valuable work in a very unostentatious manner for the benefit of the boys of London It was founded by the late Sir Robert Lucas-Tooth, who contributed a sum of £50,000 to give the scheme a start The main purpose is to train leaders for boys' organisations in order that they, in turn, may act as instructors and organisers in their various clubs All persons attending the classes must be bona fide members of a boys' club, cadet corps, or similar organisation, and must be recommended for the course by their respective club managers or officials The latest date for enrolment is Sept 15th of each year A gymnastic kit is provided for use during instruction, but remains the property of the club The course terminates in the second week of July of the following year Regular attendance from 8–10 P M on at least one evening a week is essential, as the nature of the work is progressive, for those able to attend at 7 30 P M a special vaulting class is given No payment is taken from the pupils The course consists of physical training, physical exercise, class-taking, recreational games, boxing, self defence (jiu-jitsu), and ground work Those reaching a satisfactory standard are awarded a Lucas-Tooth Badge and become eligible for a continuation course

The gymnasium (which is illustrated above) is a splendid well-ventilated room with top-lighting surrounded by apparatus The whole floor is covered with cork matting, which renders any slip during exercise almost impossible and breaks the falls which may sometimes take place beyond the space covered by the usual gymnastic mattresses For the jiu-jitsu exercises the pupils are on special grass mats as used in Japan for this method of training The cork matting also renders the movements of even a very large class unusually quiet The whole of the gymnastic fittings appear to have been judiciously chosen and carefully secured, whilst everything in the place is clean and orderly In the dressing-room each pupil is supplied with a peg in a locker, and there is ample washing accommodation, with hot and cold taps, and shower baths On the side opposite to the dressing-rooms, above a stairway, there is a coffee bar, behind a balcony provided with seats, where light refreshment can be obtained, and still higher up the stairs is a room with a punch-ball.

On the evening of my visit the advanced pupils were undergoing a special instruction course which varied from physical and gymnastic exercises to boxing and jiu jitsu. The last event was a game of (Lucas-Tooth) hand ball, which concludes every evening's work In this all those under instruction join and equal numbers appear on opposite sides It is a strenuous game and five minutes each way is quite sufficient for the players, who are, however, wonderfully keen throughout, but always good tempered In fact, the spirit in which everything was done was admirable, and the instructor was not only obeyed but willingly obeyed For the two hours under which the boys were under observation they did not appear to have a dull moment, whilst the noisy chaff and merriment amongst them when in the dressing-rooms afterwards gave evidence of their appreciation of the training and physical fitness



The Lucas-Tooth (St Olave's) *Institute at Bermondsey*

The management of the training is in the hands of Major W K Garnier, *so well known in former years* as the superintendent of physical training in the Royal Marines, and Captain W A Pinkerton (late Royal Marines) There is also an assistant, Mr J Cassford (late R N), who always appears to be where assistance is required by a hesitating or backward pupil *Visitors who would like to see* the Lucas-Tooth Institution and form their own opinion regarding it, and the work done there, are welcomed on any day in the week between 7 30 and 10 30 P M excepting *on Saturday and Sunday* I have heard of *no* institution equal to it

---

MATHEMATICS FOR NON-MATHEMATICIANS

Students of economics and statistics will be grateful to Mr D Caradog Jones and Prof G W Daniels for having written a little book on the Elements of Mathematics (University Press of Liverpool, Ltd , Hodder and Stoughton, Ltd , London, 1926, pp 240, 8*s* 6*d*), designed for those who have had only a slender training in mathematics The authors assume in their readers no mathematical knowledge beyond a matriculation standard, and the reader is led on through progressions, logarithms, and binomial expansions to coördinate geometry and calculus step by step with the intellectual equipment of a school-leaver It is not an easy path, and one which will require constant and diligent attention on every page, but at no place is help needed from any outside source The fourth part of the book provides an example of the utility of mathematical ideas in economic theory, and will afford the reader who has loyally toiled through the first three parts the satisfaction of achievement. We warmly recommend the book to all who would like to get an insight into the means by which the expert economist and statistician reach their conclusions, an insight which has heretofore been debarred to many by the impression that transcendental mathematical ability is required The book is admirably printed and arranged for the purpose in view

An Address

ON

ADAPTABILITY IN DISEASE

Delivered to the Derby Medical Society on Dec 2nd, 1926,

By GEORGE R. MURRAY, M.D. Camb.,
F.R.C.P. Lond., D.C.L.,

EMERITUS PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY OF MANCHESTER, CONSULTING PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE, AND TO THE MANCHESTER ROYAL INFIRMARY

In many diseases, and especially in those which run a chronic course, it is remarkable how well the sufferers adapt themselves to the altered conditions of their lives. This power of adaptation to adverse circumstances, or the capability of making the best of things, varies greatly in different individuals. While one sufferer from a mild chronic ailment settles down at once to an invalid existence, another with a higher degree of disability, but more courage, leads a useful and even active life for a long period. I propose, therefore, to consider briefly the adaptability of man in health and in disease, and hope to show by practical illustrations that some knowledge of his powers is a useful guide in framing a prognosis and carrying out the treatment of chronic maladies.

Reaction to Environment

In health we are constantly adapting ourselves to changes in our environment. Ready adaptability is a sign of a healthy mind and body. The late Dr J. G. Adami[1] in his Croonian Lectures, in dealing with this subject from the biological aspect, said the worker in pathological laboratories is impressed by the fact that "direct adaptation—that is specific modification in response to a specific alteration in environment within limits which will presently be laid down—is one of the basal phenomena of living matter." He showed that the variation in virulence of pathogenic bacteria is due to adaptation. The anthrax bacillus can be made to adapt itself to altered conditions in which it loses its virulence. This modified anthrax bacillus, by adapting itself to growth in a series of animals of increasing resistance, can regain its full virulence. Thiele and Embleton,[2] by the use of *anaphylaxis*, succeeded in changing the saprophytic *B. mycoides* into a pathogenic and lethal microbe for *guinea-pigs*. Thus from the lowest forms of life up to man we find that this adaptive power is present. *Adaptability is natural* to youth, and it is well that is so, as the young may be called upon to make frequent changes. Owing to the modern custom of placing many private schools near the sea instead of in the country, boys, whose homes are in the town or country, have to adapt themselves to the seaside each term. This is beneficial for some boys, especially in the summer term, but it is doubtful if there is any advantage in this change in the other two terms. Some boys find this repeated migration to the seaside very trying. At the age of about 13 a boy is transferred to a public school. Nearly all our public schools and universities are inland, some even in valleys near rivers. The health of boys at these schools is certainly excellent, and it is difficult to understand why a seaside school is considered to be so important from 9 to 13 years of age, while from 13 to 18 a boy goes to an inland public school almost as a matter of course. As years advance this power of adaptation diminishes until we find in old age a conservative frame of mind, with great aversion to changes in familiar surroundings. Normal man has powers of adaptability which have enabled him to inhabit parts of the earth where all the circumstances appear to be adverse. The Esquimaux in the far north have maintained a precarious existence for generations amid surroundings which would daunt most of us. The adaptability of our own race is notorious, as it has enabled it to establish itself in all parts of the world, and so to found the British Empire which contains every kind of climate. The ease with which human beings gradually become accustomed to life at high altitudes is remarkable. Even more remarkable is the power of adaptation to rapid ascents shown by many airmen. Careful observations made during the war made it possible to devise certain tests by means of which the suitability of candidates for flying can be gauged. By this means it is possible to ascertain if a man is fit to fly to a great height or only to a moderate elevation, or is unfit to fly at all. Equally remarkable is the adaptability of men who work in compressed air in a caisson, where the pressure is usually +30 to +35 lb., but may be as high as +45 or even +50 lb. The risk attendant on such sudden changes in pressure are, of course, greatly lessened by allowing sufficient time for gradual compression and decompression in the chamber specially constructed for the purpose. The powers of rapid adaptation to severe muscular effort can be increased by careful training in health. By properly graduated exercise in training for a boat race a healthy man greatly increases his physical efficiency in the course of a few weeks. The heart and the voluntary muscles adapt themselves to the increased effort, so that by the time of the race the sculler or crew can cover the course in a much shorter time than was possible before the training commenced. During the training it is not only a question of developing more muscular power, but also of learning how to apply it to the best advantage in propelling the boat. The circulatory, respiratory, and excretory systems have to adapt themselves to meet the tremendous strain imposed on them in rowing or running a race, be it long or short.

In the case of bilateral organs, one, by means of compensatory hypertrophy, can become capable of doing double work. This is well illustrated by patients on whom nephrectomy has been performed for disease of one kidney. The remaining kidney can do duty for both for, to my knowledge, more than 20 years. The power of adaptation varies greatly in different individuals in health and in disease. We find the same difference in those who have been permanently injured by a wound or by an accident. One man, partly by his own effort and partly by the aid of orthopædic surgery, will adapt himself and his mode of life to the loss of a limb in such a way that he is as useful a member of society as he ever was. Another man appears to be overcome by his misfortune, and resigns himself to a life of little effort or use to his fellows. In America Henry Ford has shown in a remarkable way how suitable and remunerative work can be found for men with all kinds of disabilities.

Adaptation and Prognosis

It will be generally admitted that prognosis is one of the most difficult branches of the art of medicine. Great difficulties confront us when we are asked to forecast the immediate outcome of an acute illness, and even greater when we are asked to outline the future course of events in the case of some chronic malady. I am, of course, not alluding to simple or slight forms of illness, in which a favourable prognosis can be given with a cheery optimism which does so much to encourage the relations and aids the recovery of the patient. In acute maladies rapid powers of adaptation come into play and are shown in the local and general reactions to infection. These adaptations may, however, cause the more obvious signs of the malady, as Sir F. W. Andrewes[3] said in his recent Linacre Lecture, "It is an evil that a tissue should become inflamed and that the body temperature should rise in an acute infection, but it is a lesser evil than that the infecting agent should overrun the body unchecked by any antagonistic mechanism." In many acute infections the medical man is in a similar position to that of the captain of a ship which has been caught in a severe storm at sea. The captain and his crew cannot stop the storm, but by skilful seamanship the ship is enabled to weather the storm and reach port in safety. A constant watch is kept

This unfortunate development has engaged the earnest attention of the medical department, and to assist in combating the disease it is intended to increase the staff of the Nicosia General Hospital by engaging the part-time services of a qualified oculist The malarial statistics are of great interest, and afford satisfactory proof of the value of the special antimalarial campaign conducted in 1924 Though the total number of children examined shows an appreciable increase, the spleen rate, by which the prevalence of malaria is commonly measured, fell from 13 5 *to* 9 8 *per cent* *This rate is even lower than that* recorded in 1023, since when a much stricter check has been kept on the returns rendered by the medical officers in the districts The decrease in the spleen rate for the six towns is still more marked, and the rate is now as low as 2 3 per cent

The total number of births registered during 1925 was 7803, being 23 6 per 1000 of the population, as against 8946, or 27 3 per 1000, in 1924 The deaths registered numbered 4769, being 11 4 per 1000, as against 5703, or 17 4 per 1000, in 1924 There were two Government-maintained hospitals (Nicosia and Limasol) and four Government-aided hospitals in operation during the year, as well as 19 rural dispensaries and eight branch dispensaries These dispensaries have been well attended, over 18,000 patients being afforded treatment Almost 900 patients were admitted to the Central Hospital at Nicosia, which is fitted with 56 beds, and the out-patients treated numbered more than 10,000, 122 surgical operations were performed A special feature of this hospital is the maternity side and the attention there given to the training of midwives At the close of the year 113 inmates were detained at the lunatic asylum, as against 107 at its commencement, 25 persons were discharged as cured, and 11 died, the number of new cases admitted was 12 Lunacy in Cyprus is generally of a mild form, and restraint had to be resorted to in three cases only Employment is found for some of the inmates indoors, while some are employed in keeping the grounds in order The number of lepers admitted to the leper farm—which is run on the lines of a village, with its own church, mosque, and schools—showed a decrease, the total detained at the close of the year being 80, as compared with 85 in December, 1924 There were 11 deaths, all of which were advanced cases of the disease Some of the inmates have been treated with intravenous injections of chaulmoogra oil, moogral, and preparations of antimony In nodular cases the treatment has been successful in producing the disappearance of the nodules and the growth of eyebrows Leprosy in Cyprus is well under control, and hopes are entertained that it may be possible in time entirely to eradicate it from the island. The number of children at the end of the year in the home for the healthy children of lepers was 10, all of whom remained free from any sign of the disease.

UNIVERSITY OF LONDON —Dr H S Stannus has been awarded the degree of Ph D in Science

ROYAL INSTITUTION —Next week Prof A V. Hill will continue his course of juvenile Christmas lectures on Nerves and Muscles How we Feel and Move His subjects will be the Lungs and Blood (Jan 4th), Nerves and Muscles Working Together (Jan 6th), and Speed, Strength, and Endurance (Jan 8th) The lectures are at 3 P M at 21, Albemarle-street, London, W 1

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH —On Dec 7th Prof G Lovell Gulland gave a lecture on High Blood Pressure, Albuminuria, and Glycosuria in Relation to Life Insurance It was the general rule nowadays, he said, to ask for an estimate of the blood pressure in all proposers over 50 years of age It was a useful guiding principle that any pressure above 150 mm should be regarded with suspicion, bearing in mind the fact that excitement alone might cause a rise of 20–30 mm over the true reading *Albuminuria should always be regarded as* a sign of possible renal mischief, and Prof Gulland quoted instances where an albuminuria apparently utterly unimportant had terminated in a definite *nephritis* Reviewing the subject of adolescent albuminuria he laid stress on the importance of examining the urine passed first thing in the morning If this urine was free from albumin it was, as a general rule, safe to pass the proposers He doubted the value of renal efficiency tests in these cases and in mild nephritics Even the symptomless type of glycosuria occurring in older people was not a safe risk to accept as the patients might develop the severe form Repeated tests were needed, for in a proportion of them sugar might be absent, although the patients were prediabetic cases, and should pay a heavy extra premium The only sure method of excluding renal glycosuria and lag-curve cases was by means of a full blood-sugar curve

Appointments.

CATTLE, FANNY B Sc, L R C P Lond, M R C S, has been appointed Medical Officer for the West Green district of Tottenham

HARTLEY J N J, O B E, M D, Ch B Edin, F R C S Edin and Eng, Honorary Surgeon to the Cumberland Infirmary, Carlisle

Woolwich, Metropolitan Borough of—Asst M O £600

Births, Marriages, and Deaths.

MARRIAGES

FREEMAN—DAVIDS —On Dec 21st, at the Bayswater Synagogue, Chichester place W Jack Freeman, M B, B Ch, L D S, to Freda, only daughter of Mr and Mrs S H Davids, of Hamilton terrace, N W, granddaughter of the late Rev H Davids

HUNT—MALDEN —On Dec 23rd at St James's, Piccadilly, William Thomas Hunt, M R C S Eng, L R C P Lond, to Dora Fletcher Malden A R R C, third daughter of the late Mr and Mrs W F Malden, of Boddington House, Biggleswade

McINTOSH—STONE —On Dec 18th, at St George's Hanover square, James Wilson McIntosh, M B, F R C S B Sc (P H) Edin, to Eleanor Charlotte E Stone, M B, B S, D P H Lond

DEATHS

ADAMS —On Dec 22nd, Joseph Ebenezer Adams, M S, F R C S Eng, of Harley street, surgeon to St Thomas's Hospital

DOWKER —On Nov 3rd at Helmsley, Yorkshire, Elizabeth Dowker, aged 83 years, widow of the late Frederick Woodcock Dowker, surgeon

HARVEY —On Dec 23rd, at Crawford, Godalming, Frederick George Harvey, F R C S

MASON —On Dec 19th, Henry Sinclair Mason M R C S Eng, L R C P Lond, of Glencoe, Sutton Coldfield, Warwickshire, aged 41

SCOTT —On Dec 22nd, suddenly, at Crafnant, Crowborough, Alfred Scott, M R C S L R C P, formerly of Marine parade, Brighton aged 71

WILMOT —On Dec 22nd E B Wilmot, M R C S, L R C P, of Burnham House Burnham, Bucks

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

An Address

ON

ADAPTABILITY IN DISEASE

Delivered to the Derby Medical Society on Dec. 2nd, 1926

By GEORGE R. MURRAY, M.D. Camb.,
F.R.C.P. Lond., D.C.L.,

EMERITUS PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY
OF MANCHESTER, CONSULTING PHYSICIAN TO THE ROYAL
VICTORIA INFIRMARY, NEWCASTLE, AND TO THE
MANCHESTER ROYAL INFIRMARY.

In many diseases, and especially in those which run a chronic course, it is remarkable how well the sufferers adapt themselves to the altered conditions of their lives. This power of adaptation to adverse circumstances or the capability of making the best of things, varies greatly in different individuals. While one sufferer from a mild chronic ailment settles down at once to an invalid existence, another with a higher degree of disability, but more courage, leads a useful and even active life for a long period. I propose, therefore, to consider briefly the adaptability of man in health and in disease, and hope to show by practical illustrations that some knowledge of his powers is a useful guide in framing a prognosis and carrying out the treatment of chronic maladies.

Reaction to Environment

In health we are constantly adapting ourselves to changes in our environment. Ready adaptability is a sign of a healthy mind and body. The late Dr. J. G. Adami[1] in his Croonian Lectures, in dealing with this subject from the biological aspect, said the worker in pathological laboratories is impressed by the fact that "direct adaptation—that is specific modification in response to a specific alteration in environment within limits which will presently be laid down—is one of the basal phenomena of living matter." He showed that the variation in virulence of pathogenic bacteria is due to adaptation. The anthrax bacillus can be made to adapt itself to altered conditions in which it loses its virulence. This modified anthrax bacillus by adapting itself to growth in a series of animals of increasing resistance can regain its full virulence. Thiele and Embleton,[2] by the use of anaphylaxis succeeded in changing the saprophytic *B. mycoides* into a pathogenic and lethal microbe for guinea-pigs. Thus from the lowest forms of life up to man we find that this adaptive power is present. Adaptability is natural to youth, and it is well that is so, as the young may be called upon to make frequent changes. Owing to the modern custom of placing many private schools near the sea instead of in the country, boys, whose homes are in the town or country, have to adapt themselves to the seaside each term. This is beneficial for some boys, especially in the summer term, but it is doubtful if there is any advantage in this change in the other two terms. Some boys find this repeated migration to the seaside very trying. At the age of about 13 a boy is transferred to a public school. Nearly all our public schools and universities are inland, some even in valleys near rivers. The health of boys at these schools is certainly excellent and it is difficult to understand why a seaside school is considered to be so important from 9 to 13 years of age, while from 13 to 18 a boy goes to an inland public school almost as a matter of course. As years advance this power of adaptation diminishes until we find in old age a conservative frame of mind, with great aversion to changes in familiar surroundings. Normal man has powers of adaptability which have enabled him to inhabit parts of the earth where all the circumstances appear to be adverse. The Esquimaux in the far north have maintained a precarious existence for generations amid surroundings which would daunt most of us. The adaptability of our own race is notorious as it has enabled it to establish itself in all parts of the world, and so to found the British Empire which contains every kind of climate. The ease with which human beings gradually become accustomed to life at high altitudes is remarkable. Even more remarkable is the power of adaptation to rapid ascents shown by many airmen. Careful observations made during the war made it possible to devise certain tests by means of which the suitability of candidates for flying can be gauged. By this means it is possible to ascertain if a man is fit to fly to a great height or only to a moderate elevation, or is unfit to fly at all. Equally remarkable is the adaptability of men who work in compressed air in a caisson, where the pressure is usually +30 to +35 lb., but may be as high as +45 or even +50 lb. The risk attendant on such sudden changes in pressure are, of course, greatly lessened by allowing sufficient time for gradual compression and decompression in the chamber specially constructed for the purpose. The powers of rapid adaptation to severe muscular effort can be increased by careful training in health. By properly graduated exercise in training for a boat race a healthy man greatly increases his physical efficiency in the course of a few weeks. The heart and the voluntary muscles adapt themselves to the increased effort, so that by the time of the race the sculler or crew can cover the course in a much shorter time than was possible before the training commenced. During the training it is not only a question of developing more muscular power, but also of learning how to apply it to the best advantage in propelling the boat. The circulatory, respiratory and excretory systems have to adapt themselves to meet the tremendous strain imposed on them in rowing or running a race, be it long or short.

In the case of bilateral organs, one, by means of compensatory hypertrophy, can become capable of doing double work. This is well illustrated by patients on whom nephrectomy has been performed for disease of one kidney. The remaining kidney can do duty for both for, to my knowledge, more than 20 years. The power of adaptation varies greatly in different individuals in health and in disease. We find the same difference in those who have been permanently injured by a wound or by an accident. One man, partly by his own effort and partly by the aid of orthopædic surgery, will adapt himself and his mode of life to the loss of a limb in such a way that he is as useful a member of society as he ever was. Another man appears to be overcome by his misfortune, and resigns himself to a life of little effort or use to his fellows. In America Henry Ford has shown in a remarkable way how suitable and remunerative work can be found for men with all kinds of disabilities.

Adaptation and Prognosis

It will be generally admitted that prognosis is one of the most difficult branches of the art of medicine. Great difficulties confront us when we are asked to forecast the immediate outcome of an acute illness, and even greater when we are asked to outline the future course of events in the case of some chronic malady. I am, of course, not alluding to simple or slight forms of illness, in which a favourable prognosis can be given with a cheery optimism which does so much to encourage the relations and aids the recovery of the patient. In acute maladies rapid powers of adaptation come into play and are shown in the local and general reactions to infection. These adaptations may, however, cause the more obvious signs of the malady, as Sir F. W. Andrewes[3] said in his recent Linacre Lecture. "It is an evil that a tissue should become inflamed and that the body temperature should rise in an acute infection, but it is a lesser evil than that the infecting agent should overrun the body unchecked by any antagonistic mechanism." In many acute infections the medical man is in a similar position to that of the captain of a ship which has been caught in a severe storm at sea. The captain and his crew cannot stop the storm, but by skilful seamanship the ship is enabled to weather the storm and reach port in safety. A constant watch is kept

If a leak is sprung it is counteracted by the use of the pumps, or the violence of the waves may be checked by the use of oil. In acute pneumonia we have no reliable means as yet of controlling the course of the infection or of bringing on a crisis when we wish We can, however, do a great deal by helping our patient to adapt himself to the attack by suitable nursing and feeding, and by the judicious use of medicinal and other remedies such as the occasion may demand On this occasion I shall refer mainly to chronic maladies which, be they mild or severe, will influence the whole of the patient's future life A consideration of the powers of adaptation to some chronic maladies is useful as an aid to prognosis If added to this we have some knowledge of the temperament, character, and circumstances of the patient we are all the better able to tell him what lies before him in the future. We shall, at any rate, be able to give him some general idea of what he may be able to accomplish in the way of work and recreation In framing such a prognosis the cooperation of the general practitioner, who knows the patient, his family history and surroundings, with the physician who has had special experience of the course of the particular malady in question, is important. It will be found that the prospect of being able to lead a life of some activity and pleasure acts as a powerful suggestion to a patient to face his troubles bravely and think less of them May not such a frame of mind even tend to check the progress of a chronic nervous disease? In the treatment of chronic maladies our aim is not only to do all we can to arrest or delay the progress of the disease, but also to enable the sufferer to make the best use of his time A great deal can be done in this direction by indicating how he can employ those faculties and organs left to him in working order A good example of this is seen in the modern methods of training the blind, the deaf, and the dumb, who are thereby enabled to acquire remarkable powers of doing useful work which in former times often remained undeveloped for want of suitable education This special training is now carried out on a large scale at Henshaw's Institution for the Blind and the Royal Schools for the Deaf and Dumb at Old Trafford and other similar institutions In exceptional cases the power of adapting life to loss of sight is extraordinary Take, for example, the career of the late Henry Fawcett, who was born in 1833, and lost his sight in 1858, at the age of 25, through a shooting accident In spite of this disability he held the Professorship of Political Economy at Cambridge from 1863, up to the time of his death in 1884 He was a Fellow of the Royal Society, had a distinguished political career, and was Postmaster-General in Mr Gladstone's Cabinet in 1880 He was fond of rowing, and I can remember seeing him row stroke of an eight on the Cam when I was an undergraduate at Cambridge.

Examples from the Nervous System

In recent years much attention has been paid to the problem of dealing with the feeble-minded For more than 50 years one of the main objects of the Royal Albert Institution, which was opened at Lancaster in 1870, has been to train improvable cases to adapt themselves to make the best of their limited mental powers and to apply them to learning some useful, if simple, form of handicraft In yet another direction the same principle is being applied in cases of chronic pulmonary tuberculosis It has been found by painful experience that when a man returns to his home after a course of treatment in a sanatorium and is forced by circumstances to compete in the labour market with healthy men, his efficiency is only from 25 to 75 per cent of the normal Under the strain of this competition, and the adverse circumstances of town life, many break down again. At the East Lancashire Tuberculosis Colony which has been founded at Barrowmore in Cheshire for ex-Service men and civilians, and at other similar institutions, these men are trained in carpentry, poultry-farming, gardening, and other suitable trades, under medical supervision in the country They learn to adapt themselves to do the kind and amount of work for which they are best fitted Cottages for married men and a hostel for single men have been built on the estate, so that those who wish may remain to work under the best possible conditions after their training has been completed It is, however, of the individual case as met with in practice I wish to speak in particular. As a practical illustration of what can be done, we may take a chronic disease of the nervous system, such as locomotor ataxy This malady is due to the late action of syphilis on the sensory neurons By the time the disease is recognisable more or less permanent damage has been sustained by these structures Much may be done by appropriate medicinal treatment to check or even arrest the further progress of the malady Nevertheless, at whatever stage the patient comes under observation, a certain amount of irreparable damage has been done, so that in addition to antisyphilitic and other treatment we have to teach the patient to adapt himself to his disability and make the best use of those parts of the nervous system which remain intact or are but slightly affected Owing to loss of muscular sense the ataxy is a serious disability in many cases. Muscular power may be quite adequate for all ordinary purposes, but owing to lack of control it is ineffective Efforts are instinctively made to correct this difficulty by watching voluntary movements so that sight by degrees takes the place of the lost muscular sense Prof J. B Leathes,[4] in a recent address, indicates that with the nervous system "the work of Pavlov has made one thing clear, that by a physiological reaction in it machinery may come into existence which did not exist before" It may therefore be possible, by repeated and suitable actions, not only to improve functions already performed, but create new conditioned reflexes in those who have lost some portions of the nervous system by disease We can greatly assist this process by the employment of re-education exercises, carefully adapted to the needs of each individual case One of my patients was so ataxic when he was admitted to the Manchester Royal Infirmary that he was quite unable to walk. After a few weeks' training he was able to walk about the ward, though in other respects his physical condition remained practically the same Some years ago a middle-aged man came to consult me on account of a painless swelling of one foot which prevented him from putting on his hunting boots At first he was very reticent about his past history On examination he was found to be suffering from tabes dorsalis, with a Charcot's joint Finally he gave his history, and it transpired that the malady had been present for many years, and ten years previously he had suffered severely for a time from gastric crises These ceased, and for ten years he had been able to conduct his business and to hunt and to shoot regularly. As this seemed to be a remarkable performance, I asked how he was able to do all this He admitted that in hunting he fell from his horse rather too frequently, but had sustained no serious injury In covert shooting, which is a very delicate test of coordination of the movements of the head and arms, his shooting was quite up to the average of the rest of the party, but he had to be careful to avoid taking birds passing directly overhead, as in firing at a bird in this position he was apt to lose his balance and fall on his back Another example of the long duration of the same malady was afforded by the case of a cavalry officer who, while on active service in one of the campaigns of last century, had symptoms which ultimately proved to be due to an early stage of tabes Although he was ataxic and suffered terribly at times from lightning pains, he was alive and able to travel about the world 34 years after the onset of the disease Among those who have suffered from infantile paralysis in early life we meet with remarkable examples of adaptation By the aid of exercises, massage, orthopædic operations, and apparatus, muscles are trained to carry out new functions and so to compensate for the loss of those which have become atrophied and useless I know one very plucky girl who, in spite of paralysis of both legs, learned to propel a wheeled chair, took a degree with honours at a university, followed by a special course of training in languages and in secretarial work, and now is able to go about alone and do her work in a large city.

In cases of hemiplegia, or more correctly of hemiparesis, of long standing, patients may adapt themselves remarkably. One man I know has suffered from hemiparesis from early life, but nevertheless has become an expert rock climber Epilepsy is another nervous malady from which men of great intellectual attainments have suffered and yet have become famous in history

CIRCULATORY SYSTEM.

In diseases of the circulatory system we meet with remarkable examples of adaptation It is well known that the cardiac muscle in young subjects readily hypertrophies to compensate for valvular defects resulting from acute endocarditis Compensatory hypertrophy is an important factor in diseases of the heart which occurs not only in the young but also in those past middle life, provided the myocardium remains sound. The need for compensation in these older persons may arise from sclerotic valvular disease or from the additional cardiac effort required to maintain the circulation when the blood pressure is raised in cases of renal and arterial sclerosis Familiar as these results are, it is hardly realised how long this early adaptation may be maintained in some subjects

Many years ago I was asked to examine a physician who was then about 90 years old I found marked but well-compensated mitral incompetence. He then told me that the valvular lesion had been present for 70 years It had followed an attack of acute rheumatism which had occurred at about the age of 20 He had led an active life as a consulting physician on the staff of a general hospital and lecturer at a medical school By taking reasonable care he had avoided inconvenience from this cardiac lesion throughout a very long life.

A friend furnishes another example of what can be done by sufferers from valvular disease of the heart. As a young man he had several severe attacks of acute rheumatism, in one of which I examined him. At that time he had well-marked aortic and mitral incompetence well compensated by dilatation and hypertrophy of the left ventricle During the 30 years which have since elapsed he has been very successful in business, has become a well-known Member of Parliament, and has married and brought up a family

I may also mention the case of another successful man of business who at the age of 25 had mitral incompetence, and had been taken by his medical man to consult a physician in London who gave him sound advice. For 50 years he led an active life in business and public affairs, and was able to shoot regularly each autumn. Between 70 and 75 he had one attack of broncho-pneumonia, and later on, acting on my advice, as his mitral lesion was so well compensated, he had a very successful gastro-enterostomy performed for a simple pyloric stenosis. At 75 he went out shooting while suffering from a mild attack of broncho-pneumonia, and when he gave in and sent for his doctor was found to have auricular fibrillation. When I saw him two days later he was doing well The physical signs of mitral incompetence with compensatory hypertrophy remained as before and as they probably had been for 50 years. He made a good recovery, and although the irregularity of the pulse persisted he was able to go out and shoot 40 rabbits in an hour and a half.

I may refer to a case described by Prof Edwin Bramwell[5]

The patient was a man aged 52, who early in life had an attack of rheumatic fever, and when examined was found to have typical aortic incompetence. At the age of 26 he had been advised by three distinguished physicians who all said he must take life easily and avoid physical exertion. At the end of three months he was tired of the restrictions and returned to his former mode of life, hunting three days a week, and shooting regularly His heart had never troubled him, and it was not until ten years later, when he was 62, he developed symptoms of angina pectoris from which he eventually died

In these cases so well has the cardiac muscle adapted itself to the valvular lesion that it is able to carry on until senile changes commence and the compensation fails. Even in the case of such serious conditions as heart-block, life may be prolonged, and Dr John Cowan[6] mentions that Sir William Gairdner lived for seven years with full heart-block and one of Vaquez's patients for 15 years Even when auricular fibrillation has become permanently established, life may be prolonged for years One of Dr Cowan's patients worked as a miner for 79 of the last 108 months of his life, although his auricles were fibrillating all the time

One of my patients has suffered from complete heart-block for several years and is liable to Stokes-Adams attacks Nevertheless he goes to business regularly by tram car He is well known to the conductors on the cars by which he travels, and has arranged with them so that whenever he has an attack of loss of consciousness in the car he is laid on the seat until he recovers As soon as the attack is over he goes about his business as usual

CHRONIC PULMONARY DISEASE

Among cases of chronic pulmonary disease we find many suitable illustrations We are all familiar with cases of phthisis in which arrest has taken place at an early stage and an almost normal life has been possible afterwards A young medical man who was in practice in a northern town came to consult me some 24 years ago I found physical signs of early pulmonary tuberculosis at the apex of one lung, and tubercle bacilli in the sputum On discussing the situation with him I ascertained that he could only arrange to leave his practice for six months for rest and treatment He spent this time at Davos, and occupied much of his time playing bridge out of doors with three other patients This was rather chilly work, and so a hot-water bottle was passed round to each player to warm his hands before dealing the cards Even such a short course of treatment proved most satisfactory, as the disease was arrested and he was able to resume his practice at the end of the six months He now weighs 13 st and is still at work. Several of my friends have been through a similar experience and after recovery have achieved great distinction in our profession. Such recoveries are fortunately of frequent occurrence. I wish, however, to show how some really serious cases of chronic disease can nevertheless lead active and interesting lives

In cases of chronic pulmonary disease as much as half of the pulmonary tissues may be so much involved as to be practically functionless and yet a useful life is still possible.

A good example of this was furnished by a friend who when quite a young man had suffered from fistula in ano, and presumably had been tuberculous from that time onward. He came under my observation much later in life. He then had a cough of many years' duration, though his general health was good. He had well-marked signs of chronic fibroid tuberculosis of the lung Tubercle bacilli were only found in the sputum on one occasion while he was suffering from influenza. He developed tuberculosis of one testicle which was removed The vesiculæ seminales were probably also involved, as he still continued to pass tubercle bacilli in his urine, and there was no evidence of renal infection At another time he had a tuberculous abscess at the crest of the ilium. These events were spread over a number of years, during which he was the managing director of important engineering works. He carried on his work until the natural time for retirement arrived, and lived until he was over 70 years of age. Thus, in spite of chronic tuberculosis, he carried on an active career for just as long as a normal man. He unfortunately acted as a "carrier" His only son developed pulmonary tuberculosis and died after an illness of some five years' duration. The housemaid developed caries of the spine and was reported to have died later of tuberculosis These two cases were evidently infected by a chronic carrier, but being endowed with less resistance they both died long before he did

A remarkable history was given in the case of a man of great intellectual attainments whom I only saw a few days before his death at the age of 69. He had a first attack of paroxysmal tachycardia at the age of 13 At 20 he developed tuberculosis of the right lung The attacks of tachycardia recurred at intervals for 53 years At one time he used to stop the attacks by running up a staircase. Later in life he found the best means of arresting the attacks was to drink a small bottle of champagne He had also at various times suffered from hæmoptysis He had always insisted on leading a very full life. Not only had he taken an active part in business but he was a leader in politics, and was deeply interested in philosophy Even at the end of his life he was engaged in writing a book on an abstruse subject When I saw him the whole of the right lung was extensively fibrosed with an old cavity in the upper lobe The upper lobe of the other lung was also affected The attacks of paroxysmal tachycardia had become more severe, the pulse-rate being 160 during the attacks and 80 during the intervals between them He had developed Cheyne-Stokes respiration and died a few days later

The cases I have described serve sufficiently to show how those who suffer from chronic cardiac or pulmonary disease may successfully adapt themselves to the limitations imposed by their maladies They show that in suitable cases we may urge our patients to lead fairly active lives, but naturally such cases require careful selection Sometimes the patient appreciates his own powers and limitations better than we can, and may be allowed to use his own judgment We find the highest powers of adaptation in cardiac cases in which the valvular disease has arisen in early life as the result of rheumatic endocarditis and the myocardium has escaped any permanent injury so that it is capable of undergoing adequate compensatory hypertrophy In the case of valvular lesions which develop later in life, as the result of syphilis or senile sclerosis of the valves, adaptability is much less owing to the myocardial changes which are often present in these cases, but even in these cases a quiet but useful life is often quite possible One elderly patient, who suffered from angina pectoris, told me that as long as he did not attempt to walk at more than two miles an hour he was free from pain, and at this pace he could cover as many as 15 miles in the day If he accelerated his pace, even to three miles an hour, he was apt to bring on an attack of angina He had, however, adapted himself to walking at two miles an hour, and so was able to enjoy long walks in the country without discomfort Speaking generally of cardiac and pulmonary maladies, early onset and arrest of the disabling disease leaves the greatest power of adaptation The later the disease occurs in life the less prospect there is of good adaptation Even in late cases, however, a good deal may be done to help the patient to make the best of things if not only his physical condition but all the surrounding circumstances of his life are fully considered

ENDOCRINE DISORDERS

Among diseases of the endocrine glands acromegaly furnishes an illustration of my subject In cases of this malady life may be prolonged for many years Two notable examples of the good use which can be made of these years have been furnished by members of our profession Dr Leonard Mark,[7] in his most interesting description of his own case, not only gives a graphic account of the early symptoms, but shows how a brave man carried on his work, in spite of this adversity, for many years A distinguished American surgeon, who has achieved a world-wide reputation, has also continued his career although afflicted by this disfiguring and disabling malady

A remarkable example of another disease of the pituitary gland, adiposis dolorosa, was admitted to the Manchester Royal Infirmary under my care last year The details of this case have not yet been published, but may be briefly referred to here

The patient was a married woman aged 44, who gave a history of five years illness She had four children living During the last five years she had gradually become heavier until at the time of her admission she weighed 26 st 8 lb She presented the typical appearance of a case of Dercum's disease The characteristic folds of adipose tissue were very large and the abdominal wall hung down like an apron to the level of the upper part of the knee-joint Owing to this state of affairs she could only go a few yards away from home without some means of conveyance In spite of the disability she had an active mind and was so devoted to her family and to her domestic duties that she insisted on returning to her home after a short stay in the hospital

The reason I refer to this case is that in order to adapt herself to her condition and carry on her housework she always carried a chair with her Thus she was just able to move from one part of her house to another, and then promptly had to sit down on the chair to do all her work. In this way she was able to look after her family and house in a most exemplary fashion, when many another woman would have given in and become a chronic invalid

In the treatment of Graves's disease rest is of great importance In many cases, unfortunately, owing to the domestic circumstances of the patient, adequate rest, for the long period required in such a protracted malady, is not possible In spite of such difficulties it is remarkable how well many patients adapt themselves to the best kind of life which is possible under the circumstances. By retiring to bed early in the evening and taking as much rest as possible at the week-end, many patients are able to carry on their employment and earn a necessary living throughout their illness Recovery is probably considerably delayed in these cases, but may be ultimately attained under suitable treatment In other cases the intolerance of idleness is so great that it is advisable to give some occupation, even where there is no need to work for a living. One of my patients, who passed through a severe attack of Graves's disease, of several years' duration, to complete recovery, spent part of her time in learning the Turkish language

Some of the diseases of the spleen run a prolonged course, and so call forth the powers of accommodation to the limitations which they impose Take, for example, that rare and interesting malady, polycythæmia rubra, in which, associated with a large spleen, there is a great increase in the number of the red blood corpuscles

Some years ago I saw with a friend a member of the legal profession, aged 38, who at the time was laid up with an acute attack of pain in the left side of the abdomen associated with a high temperature For seven years before this attack the increasing redness of his face had called forth uncomplimentary, but quite erroneous, comments as to his habits On examination he was found to be suffering from polycythæmia with recent acute perisplenitis The spleen extended down to the level of the umbilicus, and on auscultation friction sounds could be heard all over it He made a good recovery from the attack of perisplenitis, and 11½ years afterwards—that is, probably 18 years after the onset of the malady—he was still in the active practice of his profession

CONCLUSION

There is no necessity for me to multiply examples to illustrate my subject, as it is to those engaged in general practice that we must look for further information as to the capacities of those who suffer from chronic maladies A careful study of these capacities in each case as it comes before you, and sound advice based on these observations, will do a great deal not only to improve the condition of your patient but will enhance his enjoyment of life by instilling fresh hope when he realises that he can still do some useful work in life

I have endeavoured to show that adaptability, which is a common property of all forms of life, is a very important factor in man in both health and disease In disease, and specially in chronic disease, due allowance must be made for this capacity in framing a prognosis A practical experience of what the victim of a chronic malady can do by conscious and unconscious adaptation is of great value not only in encouraging him to make the best of his life but also in giving suitable advice as to how this may best be accomplished I wish, therefore, to make a plea for a fuller study of every case of chronic disease so as to estimate his remaining powers and possibilities as accurately as possible When his capabilities have been gauged, it may be possible in many cases, as I have shown by practical illustrations, so to order his life that it becomes far more useful and enjoyable than before In this way many a patient may be saved from drifting into an existence which is clouded by unnecessary pessimism

THE CLINICAL OCCURRENCE OF SINO-AURICULAR BLOCK.

BY PHILIP BARLOW, M D EDIN.,
BARRISTER-AT-LAW, OUT-PATIENT MEDICAL OFFICER, NATIONAL HOSPITAL FOR DISEASES OF THE HEART, LONDON

ALTHOUGH in a vast majority of cases an intermission of the pulse is due to an extrasystole, or in a minority to a slight heart-block with dropped beat, there have proved to be occasional intermissions resulting from neither of these irregularities In some of these exceptional cases a characteristic polygram and electrocardiogram has been found and the term sino-auricular block has been applied to the condition It was first used by Wenckebach in 1907[32] in describing a phenomenon comparable with auriculo-ventricular block, but where instead of an auricular beat failing to influence the ventricle (missed ventricular beat), the auricular, as well as the ventricular contraction, failed to appear on the polygram—a whole heart beat was missed In other words, there was a pause in the record equal to two cycles, suggesting that the sinus had produced an impulse which had been blocked and a whole heart beat had been lost (sino-auricular block)

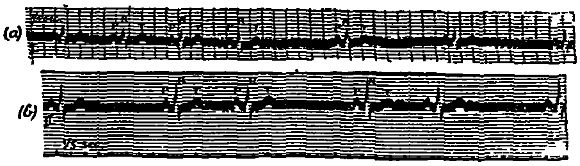
Four cases will now be described to illustrate the condition

Clinical Records

CASE I —Male, aged 65, tailor Three years ago giddiness one morning on rising, consulted doctor, who remarked that pulse was slow Pain in the back and in the right shoulder, induced by exertion, worse last six months, slight palpitation, some breathlessness and exhaustion Moderate smoker, abstainer, no history of previous illness or infection

Examination—Moderate obesity Pulse intermittent Heart sounds distant Short systolic murmur at aortic area Blood pressure, 190 systolic, 90 diastolic Slight œdema of ankles Urine normal Wassermann reaction negative Radioscopy, globular heart, apex just external to nipple line, slight enlargement to the right, aorta normal Pulse was not always irregular, but if so it showed frequent "dropped beats" Rate varied between 56 and 72 beats a minute Patient at no time was conscious of these intermissions and suffered no inconvenience from them His symptoms were ascribed to chronic arthritis, with a moderate degree of hyperpiesis When the pulse was irregular the electrocardiogram was as in Fig 1 During the 14 months of subsequent observation several electrocardiograms were taken, all of which were similar to Fig 1, with exception of the last, which showed sinus bradycardia only The same minor symptoms and signs were present and the blood pressure was systolic 170, diastolic 80

FIG 1

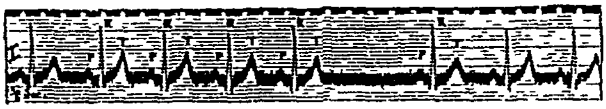


Case I —Sino auricular block In (*a*) the pause, which is almost exactly double two normal cycles, is ushered in by a slight quickening of the whole heart Thereafter there is a succession of long cycles of the same length In (*b*) bigeminy due to 3 2 sino auricular block

CASE II —Male, aged 31, medical man Had noticed irregularity of the heart for some ten years, since student days Typhoid aged 12 Life-long non-smoker and abstainer Complained of headache on walking Not fond of exercise

Examination—No abnormal cardiac signs No enlargement (radioscopy) Blood pressure systolic 120, diastolic 80 Urine normal Polygram showed sino-auricular block, confirmed by electrocardiogram (Fig 2)

FIG 2.

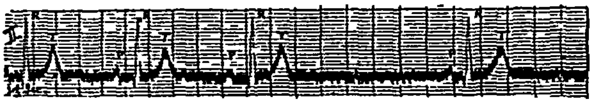


Case II —Sino auricular block In this instance the pause which measures nearly two normal cycles, is not preceded by any quickening of the heart though the cycle immediately succeeding the intermission is longer than normal

CASE III —Male, aged 51, warehouseman Influenza one year ago, not well since Two months ago felt suddenly ill and fainted, two weeks ago fainted again Absent from work eleven weeks Shortness of breath and slight pain over left margin and lower end of sternum No history of rheumatic fever Abstainer and moderate smoker

Examination—Pulse irregular showing dropped beats, rate varied between 60 and 70 beats a minute (Fig 3) Heart not enlarged No symptoms and no signs of failure Blood pressure, systolic 135, diastolic 100 After one month's observation an electrocardiogram showed no arrhythmia and at this time patient was at work and feeling well Two months later still slight irregularity was present, rate 62 beats a minute One year after the first visit an electrocardiogram showed no pauses and no arrhythmia and he had no complaints

FIG 3

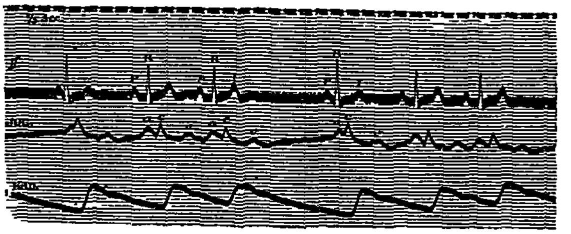


Case III —Sino auricular block The pause is almost exactly equal to the two cycles preceding it The P-R interval is shorter after the pause

CASE IV —Male, aged 41, furniture packer Pain under left breast, some breathlessness, faintness, palpitation and exhaustion, all for two years

Examination—Heart not enlarged (radioscopy) Blowing systolic murmur at the apex, pulse irregular, occasional "dropped beats," varying between 60 and 70 beats a minute (Fig 4) Blood pressure, systolic 140, diastolic 70 Wassermann reaction positive No symptoms and signs of failure Moderate smoker and moderate drinker Atropin gr 1/100 subcut reduced the number of pauses After two years' observation condition was much the same After five years' observation patient complained of nothing more than lassitude Electrocardiograms still showed sino-auricular block.

FIG 4



Case IV —Triple record of sino auricular block Electrocardiogram shows a pause nearly equalling two normal cycles The P-R and A C intervals are lengthened in successive beats before the pause This record was taken while respiration was held

The cases recorded in the literature before 1916, 14 in number, are fully dealt with by Levine[14] who

gives a comprehensive table of them, together with four of his own His collected cases are one of Mackenzie,[16] four of Joachim,[12] two of Wenckeback,[32] one of Hewlett,[11] one of Gibson,[9] one of Rihl,[22] one of Laslett,[13] two of Riebold,[21] and one of Schott [26] He points out that the arrhythmia occurred after digitalis in ten cases, disappearing when its administration ceased. In four of the eight others this drug was not given and in the remaining four there is no note on the subject, though in two it may have been given, as heart failure was present Four cases were subject to paroxysmal auricular fibrillation (two of Levine,[14] Laslett,[13] and Riebold [21]) His own cases showed pauses equal in length to multiples of the normal heart cycle

He thinks that the variation in length of the normal cycle is due to a change in the rate of the pacemaker or in the time the impulse takes to reach the auricular musculature. It is not due entirely to the latter, for the P-P interval would become gradually longer until one sinus beat would be blocked, in one of his cases, the P-P intervals become shorter before the pause (cf. Lewis), as if the conduction of the impulse improves Sometimes the intervals lengthen and then shorten without any blocked beats, and in one instance of his an impulse is blocked after a short beat. The block depends on slight sinus arrhythmia Whenever the sinus rate increases beyond a certain point the node fails to conduct the impulse to the auricles

Forms of the Irregularity

The irregularity may take several forms, (a) the heart may intermit occasionally as described above, or (b) beats may be separated into groups by regular recurrence (as in Cases 1, 2, 5, 9, 10, 32, I), or (c) there may be abrupt slowing or quickening (Case 12, also reference 16, Fig 368 [3]) Sometimes the rhythm is abruptly halved, but more often the rate is slightly more than half the rapid rate, each of the long cycles being less than two of the short ones taken together; or there may be rarely a continuous bradycardia of perhaps 30 beats per minute (Case 11), which is distinguished from other forms of slow action by the way in which it accelerates in response to exercise, doubling at once, then quickening gradually, then after exertion slowly decreasing to 80 or 70, and then halving suddenly to its original rate The most recent discussion of the several forms of this irregularity is that of Lewis [15] Levine [14] describes a case in which the intervals were usually approximately double, but sometimes simple multiples of the normal beats and occasionally longer than two normal cycles, once equalling five cycles; this appears to be a parallel instance to three cases mentioned by White,[33] (his Cases 14, 15, and 16) of complete auricular standstill, which he terms complete sino-auricular block (from digitalis), this appears to be the only reference to complete blocking Long pauses of similar nature can be produced by pressure on the vagus nerve in the neck and in morphinised dogs with excised vagus (Robinson and Draper [23]), and in dogs injected with pituitrin (Resnik [20]).

Association with Auriculo-ventricular Block.

The frequent association of sino-auricular with auriculo-ventricular block is emphasised by Lewis,[15] who says that it is too frequent to be accidental In three of his four electrocardiograms conduction is distinctly impaired as shown by the prolonged P-R interval, shortening after each long diastole (also Cases 6, 8, and IV (Fig 4)) In my four cases there is no auriculo-ventricular block, except in Case IV, where the P-R interval is prolonged (Fig 4)

There have been a great many experiments on various types of animals, both warm-blooded and cold, designed to solve the problem of the origin of the impulse and the causation of sino-auricular block Thus, in 1910 Hering [10] cooled the sinus region in dogs and since then the node has been injured, Stannius ligatures have been applied and various procedures have been adopted to cut off communication between the whole node or different portions of the node and the auricle. Cushny,[3] employed aconitine and electrical stimulation, Eyster and Meek,[7] with textile leads worked out with great care the course of negativity which passes over the heart of a tortoise, and the same authors in another paper describe a great number of experiments which seem to show, among other things, that special paths of conduction exist in the auricles Rothberger [24] concludes from some recent experiments that there are two such paths from the lower end of the node, and Poulton and Dowling [19] believe that there is some direct connexion between node and ventricle, irrespective of the contracting auricle The existence of any such tissues of conduction between sinus and auricle is strenuously denied by Lewis on both anatomical and physiological grounds

Resnik,[20] in December, 1925, conducted some experiments at the Johns Hopkins Hospital on dogs with 0 5 to 1 c cm. of pituitrin, taking one lead from the sino-auricular node itself, the other being the ordinary lead II From these (three are published) he deduces that instead of there being a block between the node and auricle, the former fails to originate an impulse at all, the result of vagal influence He suggests the name "sino-auricular standstill"

Ætiology

The ætiology of sino-auricular block is often uncertain Digitalis has been cited as one of the causes by many authors (Levine,[14] Lewis,[15] Parkinson,[18] White,[33] and Cases 2, 4, 6, 7, 8, 14, 15, 16, 18) In the cases collected by Levine [14] it is to be noted that the use of digitalis was recorded definitely in 56 per cent of them, whereas in those included here the use of the drug was noted in only 25 per cent In the last figure are included White's three cases (Cases 14, 15, and 16) of complete sino-auricular block at Massachusetts General Hospital, but in a later publication[34] he mentions that he has observed six cases in which digitalis was primarily responsible

Other occasional causes reported are tobacco (Neuhof,[17] Cases 30, 31), atropine (Smith,[28] Case 20), salicylates (Sicard and Meara,[27] Cases 3 and 4), and obscure vagal influences Levine [14] adds febrile conditions, particularly rheumatic fever and chronic myocarditis, to the list, and White arteriosclerosis and hypertension

Frequency

There is no doubt that the condition is infrequent Smith[28] says that is not so rare as the paucity of the literature would have us believe; Levine[14] states that its frequency is greater than is recognised, and this view is shared by White [33] Some observers have too readily accepted the pauses so common in pronounced sinus arrhythmia as due to sino-auricular block Smith[28] is careful to emphasise this and admits that at least two of his cases (Cases 25 and 26) might be interpreted as examples of the former

It is certain that cases are rarely seen at a clinic such as that of the National Hospital for Diseases of the Heart, though practically all irregular rhythms are investigated by the electrocardiograph Not more than 11 cases at most had been observed at the Massachusetts General Hospital from 1914 to 1922.[34]

Symptoms and Associated Conditions

There are no symptoms indicative of sino-auricular block, and patients are not conscious of the intermissions In Case 9 (Straub[10]) alcoholic neuritis was present, and this is the only mention of alcohol as a concomitant In the author's Case 2 the patient was a life-long abstainer Smith's[28] cases (19, 20, 21) were from diphtheria wards, Schirmer's[25] (Case 32) had diphtheria bacilli in the throat, and Andersen's[1] (Case 29) had a history of diphtheria Some, however, of Smith's cases were suffering from other zymotic diseases—mumps (Case 23) and pertussis (Case 24) Venereal disease is mentioned in Straub's cases and in Case 4, and also in the former the fact of treatment with mercury, the Wassermann reaction was negative, but the Sachs Gorgi positive In Case 4 the

TABLE OF CASES REPORTED IN THE LITERATURE, 1916–26

No	Case and associated conditions	Special features
1	Stokes Female, 36 Arteriosclerosis, anginal pains	History of rheumatic fever and typhoid 3 2, 4 3, 5 4 types Atropine effects Polygrams
2	Danielopolu Male, 70 Slight cardiac failure, emphysema	Digitalis used. History of rheumatic fever 3 2, 4 3, 5 4 rhythms Atropine effects Swallowing temporarily abolished block
3	Sicard and Meara	Occasional dropped beats Salicylates
4	Sicard and Meara Male Acute rheumatism, endocarditis	Digitalis used Salicylates Polygram
5	Eyster and Evans Male, 31 Healthy	2 1 3 2, 4 3 types Atropine effects Nodal rhythm present Vagal stimulation effects
6	Parkinson Male, 35 Anginal pains	Digitalis used History of rheumatic fever and typhoid Occasional pauses Atropine effects Pressure on eye and vagi had no effect A-C interval increased.
7	Straub Male, 31 Aortic incompetence, mitral stenosis, nephritis	Digitalis used Occasional pauses Electrocardiogram
8	Straub Male, 59 Syphilis, gonorrhœa, iritis	Digitalis used. 2 1, 3 2 rhythm P-R interval increased
9	Straub Male, 29 Dyspnœa	History of rheumatic fever 3 2 type Quinidine temporarily abolished block Electrocardiogram
10	Straub Male, 75 Alcoholic neuritis	3 2, 2 1 type Electrocardiogram
11	Gallavardin et Dumas Male, 37	Pulse rate 34 beats a minute Rate doubled on violent exertion Block temporarily abolished by swallowing
12	White Male, 34 Athlete	Halving of rate one minute after running ¼ mile
13	White Female, 33 Obscure cough.	Electrocardiogram
14 15 16	White	Three cases of complete sino-auricular block at Massachusetts General Hospital Digitalis used in each.
17	White Aged 56 Cardiosclerosis, slight failure	—
18	Straub Male, 47 Dyspnœa, cardiac pain	Digitalis used Extrasystoles Some of the pauses due to ventricular escape
19	Smith Aged 5 Three months after diphtheria	Electrocardiogram
20	Smith Aged 4 Acute diphtheria	Atropine and strychnine caused block. Electrocardiogram.
21	Smith. Aged 8 Diphtheria, convalescent	Mental stimulation caused block to disappear
22	Smith. Aged 6	Block disappeared on fretting
23	Smith Aged 6 Mumps	Fourteenth day after swelling observed
24	Smith. Aged 4 Pertussis	Block present 13th day between paroxysms
25	Smith None	Present after exercise
26	Smith Aged 19	" " "
27	Brown. Male, 11 Acute arthritis, heart enlarged.	Salicylates Frequent pauses Atropine effects Vagal stimulation effects Electrocardiogram.
28	Poulton and Dowling Left hemiplegia, hyperpiesia	History of recent lobar pneumonia Block persisted for 12 years No atropine effects, vagal stimulation effects present
29	Andersen Male, 25 Heart enlarged.	History of diphtheria, scarlet fever, and influenza 3 2, 4 3 rhythms Quinidine temporarily abolished block.
30	Neuhof	Tobacco
31	Neuhof Myocarditis, cardiac failure	"
32	Schirmer Heart enlarged.	2 1, 3 1 types Diphtheria bacilli in throat
I	Male Aged 65 (see text)	Occasional dropped beats, also 3 2 type Observed 14 months Electrocardiogram
II	Male Aged 31 (see text)	Occasional dropped beats
III	Male Aged 51 (see text)	Occasional dropped beats P-R interval shorter after the pause Observed one year
IV	Male Aged 45 (see text)	Occasional dropped beats P-R interval lengthened before the pause Observed five years

Wassermann reaction was positive, though were there no clinical signs of syphilis There was a history of rheumatic fever in seven (Cases 1, 2, 3, 4, 6, 9, 27) and of typhoid in three (Cases 1, 6, 11). The general association is very much as outlined by Levine[14] and White[34]—(supra) myocarditis, rheumatism, general cardiosclerosis, and febrile conditions, but in many there is no discoverable cause or association of importance

Atropin is shown to have temporarily abolished the block in five cases (1 2, 5, 6, 27), swallowing in three (2, 5, 11), quinidine in two (9, 29) Pressure on the vagi increased the irregularity in three cases (5, 27, 28) and on the eyeball in two (11, 27) It is noted that in one case[6] pressure on vagi and on the eyeball had no effect Exertion, physical or mental, increased the arrhythmia in four cases (6, 22, 25, 26), and in one [21] caused it to disappear In one case[11] the heart-rate doubled on exertion and in one[12] it halved one minute after violent exercise

Diagnosis

The condition can only be diagnosed by graphic methods A slight preparatory quickening of the whole heart, followed by a pause equalling approximately *two normal heart cycles with a total absence* of "P" or "a" waves, occurring either alone or grouped, as above, is seen on the record. Sino-auricular block must be differentiated from (*a*) the extrasystole, (*b*) the occasional dropped beats of auricular-ventricular heart-block, (*c*) sinus bradycardia with ventricular escape, (*d*) a blocked premature auricular contraction, and (*e*) sinus arrhythmia, which often simulates sino-auricular block very closely Resnik[20] obtained in his experiments practically complete transitions between sino-auricular "standstill" and sinus arrhythmia He regards the condition as a special form of sinus arrhythmia

Prognosis and Treatment

There is little or nothing in the literature on the subject of prognosis Schirmer's case (Case 32) was reported as recovered and the four cases here described have shown no serious signs

No treatment is necessary. The condition is not pathological, is present in a few hearts, and may be regarded as physiological It does not by itself necessitate any interference with the patient's mode of life and can be neglected in considering his future

Summary

1 Four cases of sino-auricular block are described and a tabular summary of published cases since 1916 is furnished 2 It is a rare cause of intermission of the pulse, in which a whole heart beat fails to appear, and it is only recognisable by graphic methods 3 Atropin usually abolishes the block temporarily Pressure on the bulbus oculi and also on the vagus has varied effects 4 Ætiologically no one factor is responsible, though many cases are definitely due to digitalis administration Other suggested causes are the use of tobacco, salicylates, and infective conditions 5 There are no characteristic symptoms in association, and it produces none 6 The condition may be present without any symptoms or signs of cardiovascular disease, but it is often accompanied by slight grades of auriculo-ventricular block or other signs which indicate associated myocardial disease.

I wish to express my thanks to Dr John Parkinson, physician to the hospital, for permission to use the four cases shown and for his help

GASTRIC SECRETION IN GRAVES'S DISEASE

BY HENRY MOLL, M D ROME, M B , CH B LEEDS, M R C P LOND.,
MEDICAL TUTOR AND REGISTRAR, UNIVERSITY OF LEEDS,
AND
R A M SCOTT, M B , B CH CAMB.
LATE HOUSE PHYSICIAN, LEEDS GENERAL INFIRMARY

REHFUSS tests were made on 50 cases of hyperthyroidism Of these 22 showed achlorhydria They comprised 19 cases of Graves's disease and three of forme fruste Of the 19 cases of Graves's disease with achlorhydria, 15 were of more than two years' standing Hypochlorhydria occurred in 15 cases Of these, four were acute cases of Graves's disease, all of less than 11 months' standing; six of Graves's disease of one year or more, four of toxic adenoma, and one of puberty hyperplasia Normal chlorhydria occurred in nine cases Of these, three were acute cases of Graves's disease of less than one year's standing, one of chronic Graves's disease undergoing X ray treatment, two of toxic adenoma, two of forme fruste, and one of puberty hyperplasia High normal secretion was found in only four cases, the acidity (free HCl), however, never reaching higher than 65 (N/10 NaOH) These cases comprised one of puberty hyperplasia, one of forme fruste, one of toxic adenoma, and one of chronic exophthalmic goitre Table I is a summary of these cases

TABLE I

—	Achlor-hydria	Hypo chlor hydria	Normal	High N
Chronic Graves's disease (of more than two years' standing)	15	6	1	1
Acute Graves's disease (of less than one year's standing)	4	4	3	—
Toxic adenoma	—	4	2	1
Forme fruste	3	—	2	1
Puberty hyperplasia	—	1	1	1
Total	22	15	9	4

The average duration of symptoms in cases of Graves's disease with achlorhydria was 2 9 years, in cases of Graves's disease with hypochlorhydria, 1 1 years, of Graves's disease with normal secretion, 0 5 year Thus in the more acute cases the gastric secretion was least diminished. This suggests that the diminution of HCl secretion occurs in the course of the disease, and is not, in the majority of cases, a predisposing cause

Table II is a summary of the charts of the 50 test-meals

TABLE II

—		Achlor hydria	Hypo-chlor-hydria	Normal
Mucous secretion		N	N	N
Percentage of cases with rapid emptying stomach		90	50	24
Time of disappearance of starch or sugar in hours		0 89	1 5	2 1
Percentage of cases with much bile		60	50	40
Free HCl (N/10 NaOH)	(a)	—	15	47
	(b)	—	20	65
	(c)	—	5	35
Total acidity (N/10 NaOH)	(a)	27	42	59
	(b)	40	60	80
	(c)	15	32	40

N = normal (a) average, (b) maximum, (c) minimum

The chief conclusions to be drawn from these findings are (1) There is a constant tendency towards subnormal or absent secretion of HCl in Graves's disease (2) The secretion of HCl in cases of *toxic adenoma and puberty hyperplasia* is usually normal or subnormal but never absent (3) There is a strong tendency to regurgitation of bile in Graves's disease (4) The stomach empties very rapidly in Graves's disease (5) The *total acidity* is usually high in cases of achlorhydria

The rapidity of emptying of the stomach in Graves's disease is sometimes extraordinary In two cases the stomach contents passed into the duodenum in less than a quarter of an hour Each of these two cases showed achlorhydria and bile in practically every sample It was thought that the stomach-tube might have passed into the duodenum, but on repetition of the tests similar results were obtained A third test was made in one case when the patient was beginning to respond to treatment, and in this case starch was found after a quarter of an hour and sugar up to half an hour.

Explanations of Deficient Secretion of HCl in Graves's Disease

There are four plausible explanations of the lack of secretion of HCl in Graves's disease

The first is that the general toxic state of the patient leads to a catarrhal condition of the stomach This produces a physical obstruction to the work of the oxyntic cells, and the dilution and bathing of the stomach contents with mucus prevent the chemical stimulus to the secretion of gastric juice The resultant low acidity allows rapidity of emptying of the stomach through lack of chemical stimulus to the pylorus The objection to this theory is that the mucous secretion in the Graves's disease cases was not found to be greater than in cases with normal chlorhydria

The second explanation is that the low secretion of HCl is a congenital defect and provides a mode of entry into the intestinal tract for living bacteria The problem may be viewed in the same light as is the problem of achlorhydria in pernicious anæmia McCarrison [2] has put forward many suggestions on behalf of this theory He points out that correction of intestinal stasis has cured several cases of Graves's disease, even the wearing of an abdominal belt in a case of visceroptosis has effected a cure

A number of cases have followed acute infectious diseases when resistance to bacterial infection is low Foci of infection in the mouth or nasopharynx were discovered in 70 per cent of the present series of cases of Graves's disease

In Graves's disease there is an increase in the number of lymphocytes around the adenoid portions of the thyroid and in the lymphocytic aggregates at the hilum, together with a general increase in the

lymphoid tissue of the spleen, parathyroids, liver, kidneys, bone-marrow, and intestines This may fairly be considered a reaction to bacterial infection.

There are two main objections to this theory. The first one is that the diminution of HCl secretion occurs in the course of the disease, the second that the achylorhydria in 60 per cent of cases is only an apparent one In many cases, therefore, the achlorhydria cannot be considered as a predisposing cause of hyperthyroidism, although, at a later stage of the disease, it may enable toxins to be elaborated in the intestinal tract which will help to maintain the state of thyroid toxæmia

The third explanation is that the absence of HCl is due to regurgitation of duodenal contents In many of the cases a very great frequency of occurrence of bile is noted, and in 60 per cent of cases of achlorhydria bile was found in more than half the samples These cases also showed a relatively high total acidity Total chlorides were estimated in four cases of achlorhydria, in two of these the value was low and the chloride curve ran a more or less horizontal line, whilst in the other two the chlorides were found to be high and the curve to be of the climbing type, suggesting duodenal regurgitation A chloride estimation was also made on four cases of hypochlorhydria and on two cases of normal secretion, and in all these cases the high chloride values warranted some degree of duodenal regurgitation, which, in one or two cases, was very considerable indeed It was also found that the presence of bile was a fair indication of duodenal regurgitation, as the total chlorides attained their highest values in those samples containing bile Thus one may conclude that 60 per cent of the cases of achlorhydria, found in Graves's disease, are apparent achlorhydrias due to duodenal regurgitation

The rapid emptying of the stomach, found in Graves's disease, has already been noted This hurrying of the gastric contents is in accordance with the hypermotility of the lower intestinal tract leading to diarrhœa, a very common symptom in Graves's disease A patulous pylorus probably also accompanies the hypertonus of the stomach, and the two conditions, acting together, explain how duodenal contents may regurgitate in large amounts and give rise to an apparent achlorhydria or to an apparently low acid secretion

The Sympathetic Factor in Gastric Function

If a large number of achlorhydrias may be attributed to duodenal regurgitation, there still remain, however, 40 per cent of cases requiring an explanation As the number of true achlorhydria found in Graves's disease is five times the average incidence of achlorhydria in the normal person, it is suggested that the low or absent secretion of HCl in these cases may be caused by an inhibitory action due to overstimulation of the sympathetic system To test this theory, the sympathetic systems of two cases of hyperchlorhydria were stimulated by injections of adrenalin and the effect on gastric secretion was noted

The first was a case of dyspepsia of vagotonic type A test-meal showed the HCl curve to be of the climbing type and reaching 90 (N/10 NaOH) Bile was present in 3 out of the 13 samples taken at quarter-hour intervals Starch was *still* present at the end of the test—viz, three hours A second test was made, and at the end of the first hour a subcutaneous injection of ♏ xv, 1 in 1000 adrenalin was given. The chart showed a surprising change Following the injection of HCl curve dropped from 70 to nil. In a quarter of an hour the curve rose *again as* high as before, but at the end of the three hours fell very low and returned to zero No starch was found after two and a half hours Of the samples following the injection all but one contained bile

Rather impressed by this but in *some* doubt whether the sympathetic stimulation was due to adrenalin or the prick of the needle, it was decided to treat a similar case with adrenalin continued over some time

A patient with symptoms of duodenal ulcer was given a test-meal. The chart showed a high and climbing curve, the HCl reaching 88 (N/10 NaOH) To him were administered ♏ v of 1 in 1000 adrenalin subcutaneously every four hours, until, after the fifteenth injection, there occurred abruptly, symptoms of sympathetic stimulation—to wit, tachycardia, palpitation, and tremor Thereupon a second Rehfuss test was made This showed hypochlorhydria The HCl reached 23 (N/10 NaOH) as a maximum, the stomach emptied *only* 15 minutes sooner, and there was no alteration in the amount of bile, which was very small and occasional in both cases It is interesting to record that following the injections, the patient felt considerably better and was free from pain for several days

If stimulation of the sympathetic causes this change in gastric function, then paralysis of the sympathetic should have the opposite effect The drug best known to have such an action is nicotine It has already been pointed out how smoking increases the secretion of HCl, and it was found interesting to make Rehfuss tests on six cases of post-encephalitic Parkinsonism undergoing prolonged nicotine treatment (administered hypodermically in doses varying between 1/30–1/5 gr) in an attempt to reduce plastic tone The tests were made before and after treatment. One case showed no change The other five all showed an increase in HCl secretion In one case the HCl *rose from* 60 (N/10 NaOH) *to* 110, *after* ten days of nicotine treatment, 1/5 gr of the drug having been administered thrice daily

There is a certain amount of evidence to show the part played by the sympathetic in gastric secretion It is an accepted fact that the vagus and the sympathetic have an antagonistic effect on the motility of the stomach It is reasonable to suppose that their effects (if any) on gastric secretion are opposite Pavlov's[3] experiments have shown how secretion stops in frightened or enraged animals, presumably under strong sympathetic stimulation R Gaultier[1] has observed in the dog that section of the splanchnic nerve (sympathetic) always causes a pronounced hyperchlorhydria and that excision of the solar plexus has a similar effect He concludes that the sympathetic, by means of the circulation, is an important factor in regulating the acid secretion of the stomach Shortly before this, Shupfer[4] had drawn the same conclusion based on experiments which showed that section of *the anterior and* posterior roots of the fifth to the ninth dorsal segments (from which the sympathetic arises) caused a constant hyperchlorhydria

In concluding, one may say that the low acid secretion and the achlorhydria, which have been nearly a constant feature in the present series of cases of Graves's disease, can be explained by a twofold mechanism One, associated with overaction of the vagus, and causing both hastening of the gastric contents in passing through the stomach, and duodenal regurgitation. This would explain the cases of apparent achlorhydria The other, by a direct inhibitory action of the sympathetic on hydrochloric acid secretion and causing a true achlorhydria

Both the vagal and sympathetic types of achlorhydria may be ascribed to profound changes in the tone of the vagus and sympathetic nerves which are well known to occur in Graves's disease and which give rise to the other signs of hyperthyroidism

Summary

(1) Rehfuss tests were made on 50 cases of hyperthyroidism (2) Of these, 22 showed achlorhydria, 15 hypochlorhydria, 13 normal or high normal chlorhydria (3) The average duration of symptoms in achlorhydric cases was 2 9 years, in hypochlorhydric cases 1 1 years, in cases with normal secretion 0 5 year. This suggests that the diminution of HCl secretion occurs in the course of the disease, and is not a predisposing cause (4) Of the cases of achlorhydria, 60 per cent were due to duodenal regurgitation (5) An explanation has been offered of the cases of true achlorhydria found in Graves's disease

DEVELOPMENT OF A TUMOUR (FIBRO-SARCOMA) AFTER INJECTION OF SALVARSAN.

By HANS FREDRIK HARBITZ, M D,
HOUSE SURGEON IN THE MUNICIPAL HOSPITAL OF BÆRUM
SANDVIKA ST, OSLO, NORWAY

CHEMICAL irritants are relatively often found to be contributory causes in the formation of tumours, in most cases epithelial tumours (for example, skin-cancer), but also sarcomas Arsenic, when introduced into the organism, is to some extent deposited in the skin, and this renders it probable that eventual changes are most likely to occur there Thus we have the arsenic melanoses and hyperkeratoses following on long-continued administration of arsenic, and we find skin-cancer in consumers of arsenic This was pointed out by Hutchinson (1887), who observed skin-cancer in patients with psoriasis, to whom arsenic had for years been administered per os In order to investigate the question whether arsenic had really any tumour-producing power, Leitch and Kennaway [1] have fed rats and mice with food containing arsenic, but without any result They then proceeded to paint the skin with arsenic (alcoholic solution of arsenite of potassium) Only in one out of many experiments did they observe after about 12 weeks the growth of a tumour, which proved to be a squamous-cell carcinoma, and there was also metastasis to the lung The significance of chronic inflammations in the formation of tumours has also been recognised, most often epithelial tumours, although indubitable sarcomas, have also occurred [2]

The whole matter may be regarded from the viewpoint of Virchow's theory of irritation, and if we in the case about to be described assume that the arsenic injected has played a part in the subsequent development of a tumour, then the following statement by Borst [3] is very much to the point: "One may hold that by chemical and other irritations chronic inflammatory and regenerative processes may be maintained, during which there will occur such changes in the character of the cells as will make them incline under certain circumstances to malignity"

Clinical History

Female, aged 46, admitted to Drammen City Hospital, Norway, in October, 1925 Had an apical pulmonary affection eight years ago, in 1909 double salpingitis In November, 1910, she was admitted to hospital suffering from syphilis, with a genital chancre and a maculo-papulous squamating exanthema For this she was given on Dec 31st an injection of the salvarsan preparation "Hata 606," 0 50 g in the left interscapular region, whereupon the exanthema disappeared after a month In the following year she was again admitted, suffering from mucous tubercles on the genitals and in the mouth, and was treated with mercury On that occasion nothing was recorded respecting the site of the previous injection She now states that after the injection 15 years ago she got a "lump" at the place of injection, which had continued without appreciable change until about a year ago, when after an injury it began to increase in size, and has since grown steadily, sometimes causing slight pain

Condition on Admission—Healthy appearance, lungs, heart, and urine normal In the left interscapular region there is a well-defined, firm tumour, as large as a goose-egg, not tender to touch, and covered by normal, movable skin The tumour can be moved slightly from side to side

Operation—On Oct 22nd the tumour was removed by a longitudinal incision made through the *fascia and muscle* It was surrounded by a fibrous capsule, so that it could be extracted apparently in its entirety The wound healed rapidly. Nov. 25th No sign of recurrence

Pathological Report (Pathological Institute of the State Hospital, Prof Francis Harbitz)—Ovoid tumour, 11 × 5 × 4 cm in size, surrounded by a thin capsule, in part slightly adherent to surrounding connective tissue The surface is somewhat uneven and the cut surface greyish white and firm *At one point some necrosis At* one pole another tumour as large as a nut was found, separated from but *immediately adjacent* to the main tumour Microscopical sections of the tumour at different places showed *numerous, mostly long-shaped*, connective tissue cells and a fibrillary intercellular substance At some places *the cells lay close together* and showed atypical forms At other places there are more regular, proliferating connective tissue cells of *tumour-like* nature Section of the soft portion showed a more myxomatous connective tissue without *atypical cells* Only slight infiltration of leucocytes, at many places none being seen Diagnosis Fibrosarcoma

Discussion

"Hata 606" is the name first given to salvarsan, and it contains about 30 per cent of arsenic From the history of the case it was impossible to avoid the suggestion of an ætiological connexion between the intramuscular *injection* 15 years ago and the subsequent development of the tumour at the same spot The tumour was, therefore, sent to the Pharmacological Institute of the University of Oslo, and was examined for arsenic by Prof Poulsson with the following result.

> There were small quantities of arsenic in the tumour The examination was carried out by cutting out 50 g of the central portion of the tumour with sterile scissors, destroying the organic substance by means of hydrochloric acid and chlorate of potassium, and otherwise proceeding in the usual manner In the Marsh apparatus there appeared after some time a scanty coating with the appearance characteristic of arsenic, which on introduction of *dry* hydrogen sulphide assumed under gentle heat the yellow colour of arsenium sulphide

In the normal human body arsenic is of constant occurrence in very small quantities, especially in the thyroid gland, in the skin and hair, being probably *conveyed in the food* Gautier [4] estimates the total quantity of arsenic in the human body at 0 43 mg, 0 17 mg being found in the thyroid gland In the rest of the body, and mainly in skin and hair, there should thus remain about ¼ mg of arsenic In normal musculature Gautier and several other investigators found no arsenic [5]

Prof Poulsson states that, although no quantitative analysis was made, yet from the *investigation* made and from the distinctness of the test it may with certainty be assumed that the detected quantity of arsenic exceeds the amount normally present, otherwise, in *the relatively small portion of* tissue examined (50 g of tumour substance), arsenic could hardly have been detected so distinctly by the method employed As there was no evidence of the introduction of arsenic from other sources, it may be assumed that some of the arsenic injected must have remained at the place where the tumour afterwards appeared What is therefore remarkable in the first place is the long time the arsenic has persisted locally. In Poulsson's "*Pharmacology*" it is stated that some of the salvarsan passes through the body unchanged, and appears as such *in the urine from 5 to 30 minutes* after intravenous or intramuscular injection, while some of it goes over to form unknown combinations The main quantity is excreted in the course of the first few weeks, the remainder leaves the body slowly, so that the urine *reacts to the arsenic test* for several weeks, after arsenic poisoning for several months

The next point of interest *is* the tumour itself According to the patient's statement, an infiltrate remained at the point of injection for about 14 years, and, after a trauma (about which, however, there is room for doubt), it began to grow The infiltrate itself probably implied a chronic reactive inflammation, and doubt might, therefore, be entertained whether the tumour was not of inflammatory nature Judging from its clinical behaviour—its distinctly progressive growth, appearance, limitation by a capsule, as well as the whole microscopical picture with the scanty infiltration of leucocytes, localised only to some spots, it seems exceedingly probable that there has existed a genuine tumour, in this case mainly a fibroma, but at some places more of sarcomatous nature

THE TITRATION OF SCARLET FEVER ANTITOXIN IN RABBITS

By H J PARISH, M D, M R C P Edin
and
C C OKELL M C, M B Camb, M R C P Lond
(*From the Wellcome Physiological Research Laboratories*)

It is generally admitted that one of the most urgent needs in connexion with recent work on scarlet fever is a method of titrating toxin and antitoxin by some means other than on human subjects Up to now the only promise of an animal test has come from the researches on goats of Kirkbride and Wheeler,[1] but the work has not yet been generally confirmed and the method is complicated by many difficulties

Many attempts have been made in the past to measure in various laboratory animals, particularly mice and rabbits, the protective value of antibacterial sera against living cultures of streptococci The results of most of this work in our own and other workers' experience have been disappointing It has been found, however, that rabbits could be killed with reasonable regularity by the intravenous injection of the "Dochez" streptococcus and certain other scarlet fever strains If the rabbits were injected intravenously 4 to 6 hours previously with an adequate amount of scarlet fever antitoxin, death did not take place or was delayed beyond the sixth day 10 c cm of a 20-hour tryptic digest broth culture of the *Streptococcus scarlatinæ*, given intravenously, killed in successive experiments 70 per cent of 63 rabbits of medium weight within 48 hours and 92 per cent within six days 5 c cm. of unconcentrated and 1 c cm or less of concentrated scarlet antitoxin protected the great majority of rabbits The protected animals, which survived for a longer period than six days, almost always developed a purulent arthritis of one or more joints, from which a pure culture of the streptococcus could usually be obtained

With sera other than streptococcal no protection was obtained, with various antistreptococcal sera, other than scarlatinal, from 17 to 29 per cent of the rabbits were protected by doses of 5 c cm of serum This group included unconcentrated sera prepared against streptococci of erysipelas, puerperal fever, and pyogenic infections Seventeen rabbits were injected with 5 c cm of a serum prepared by immunisation with filtrates of a strain of *Streptococcus pyogenes* Of these, 29 per cent survived This strain was isolated by Sir Frederick Andrewes from the septic finger of a nurse at St Bartholomew's Hospital It produced a toxin which gave a reaction indistinguishable from the Dick reaction in Dick-positive individuals, but no reaction in Dick-negative individuals, it had, therefore, a close antigenic relationship to the scarlet fever group of streptococci

Having found that specific scarlet fever antitoxins could be distinguished from other sera, an attempt was made to compare scarlet fever antitoxins of different values as tested by the Schultz-Charlton and passive immunity methods Three pairs of sera which had been placed by means of human tests in "order of merit" were compared Of two unconcentrated sera "A" was considered better than "B" on human tests Serum "A" in a dose of 10 c cm turned 13 out of 14 "Dick-positive reactors" negative within 24 hours, and 0 2 c cm of a 1 in 500 dilution blanched the rashes of 7 out of 15 patients Serum "B" turned none of 4 patients Dick-negative and blanched poorly the rashes of 4 out of 15 patients In the rabbit test 15 rabbits were injected with each of the two sera in corresponding doses—viz, 10 c cm, 5 c cm, and 1 c cm Ten of the rabbits in the "A" batch survived, but 5 only in the "B" batch

The second pair of sera consisted of a concentrated batch "D," and an unconcentrated, "E" By human tests it was found that with 2 5 c cm of serum "D," ten Dick-positive reactors became negative over night, and still gave a negative Dick test when retested on the twelfth day, whereas serum "E" in a dose of 10 c cm turned only 7 out of 10 patients negative In the rabbit test the percentages of survivals were at every dose higher for serum "D" than for serum "E" A dose of 1 c cm of serum "D" saved all three rabbits injected, while it took 10 c cm of serum "E" to produce the same result With a third pair of sera the same agreement between human and rabbit tests was found

We have not yet had an opportunity of comparing sera known to be efficient in the treatment of scarlet fever with sera which proved unsatisfactory, though this is the crucial test of any method of titration

In analysing these results, it was obviously most important to decide whether the protection of the rabbits was due to antitoxin per se, or to some other protective antibody produced in the horse in response to immunisation

The following observations have a bearing on this question (1) Many of the sera were experimentally made by injecting horses with bacteria-free filtrates of young cultures of streptococci, and were therefore as purely antitoxic as could be prepared (2) The serum of rabbits highly immunised against washed (toxin free) streptococci, though rich in agglutinins, had no protective value (3) Human convalescent serum had a small but definite protective value (4) The protective power of antitoxic sera against culture was lost if the serum had previously been treated with an adequate amount of toxin (5) Scarlet fever toxin, when given intravenously in sufficiently large quantities, killed 80 to 100 per cent of rabbits Scarlet fever antitoxin protected rabbits from death due to toxin, while normal horse serum and concentrated diphtheria antitoxin were without protective value These observations possibly provide a means of titrating scarlet fever toxin and antitoxin without the use of culture

These results, further details of which will be published at a later date, in conjunction with the agreement obtained with human tests, suggest, if they do not prove, that the test is a measure of "antitoxin" per se

It may be added that though scarlet fever antitoxin protects rabbits against hæmolytic streptococci from cases of scarlet fever, it also protects against the septicæmia due to certain other hæmolytic strains which have no obvious connexion with scarlet fever It is not clear at this stage, therefore, to what extent the test can be used conversely to identify the scarlet fever streptococcus Before this question can be answered it would be necessary to have much more information about the immunological relationships between streptococci of the hæmolytic group and their toxins than is yet forthcoming

Summary

(1) Rabbits can be killed with considerable regularity by intravenous injections of broth cultures of the *Streptococcus scarlatinæ*

(2) A test is described by means of which scarlet antitoxic sera can be compared among themselves

---

[1] Kirkbride, Mary B and Wheeler, Mary W Proc Soc Exper Biol and Med, 1924, xxii, 86

and distinguished from other sera Scarlet fever antitoxin protects rabbits against the more acute phase of the septicæmia due to the streptococcus. Later, many of the protected animals develop arthritis and other manifestations of subacute infection

(3) The test is a quantitative one, "good" sera can be distinguished from "poor"

(4) In the case of three pairs of antitoxic sera differences were detected by the rabbit test corresponding to differences on human test

(5) The method, if confirmed in further work, may provide a means of titrating scarlet fever antitoxic serum in the laboratory.

PULMONARY TUBERCULOSIS

A SIMPLE PREVENTIVE

By W B VAILE, M R C S. Eng.,
MEDICAL OFFICER TO THE CHURCH ARMY SANATORIUM FOR BOYS, HEATH END, ALDERSHOT

SEVEN years ago I began to investigate the incidence of pulmonary tuberculosis in families exposed to infection, trying to find the principle of selection with a view to the prevention of the disease I began by assuming that every case of pulmonary tuberculosis was as certainly the result of infection as every case of measles Next, that if several persons are equally exposed to the same infection under the same conditions for the same time, their escape or infection must depend on the resistance of the individual. And the task I set myself was to find the secret of that resistance

My opportunities have been only those of a country practitioner in charge of a sanatorium for boys with about 10 beds I chose large families (to avoid freak results) and small houses (to ensure fairly equal exposure of each member) It is, of course, impossible that all should inhale the same number of bacilli per breath or per day, but it is sufficient for our purpose that they all live and sleep at home, healthy and infected mingling in the ordinary intercourse of daily life They will all inhale the same strains of bacilli mixed in the same proportions Whether those bacilli are many or few matters not, since everyone must breathe the air in that small home The attack is the same The conditions under which they have to meet it are the same All the countless factors of ventilation, sunlight, good or bad food, cleanliness, careful or careless coughing and spitting, &c, need not be taken into account They were the same for all And the hereditary resistance of the family, or at any rate of the children, may be assumed to be the same Everyone starts fair It is, in fact, a classic race and not a handicap

Search for Some Common Factor

After some years of such a test we need only inquire into the health of each member to know which have the better resistance I wished to find some common factor which all or most of the survivors possessed and all or most of the infected lacked None of the usual ætiological factors seemed to fit, though any one of them would account for a case here and there Nothing was of general application until I began to ask a very simple question—six words only—"Do you eat fat—or not?" I found that most of the healthy survivors had always done so, while the great bulk of the infected, the dead, and the dying had had a lifelong dislike for fat and had avoided it as far as possible all their lives In family after family I found this trivial peculiarity dominating the situation, brushing aside other influences, forming the dividing line between healthy and infected, living and dead In many families all the fat-eaters had escaped, while all the fat-shy (to use a convenient expression) had become infected In some the only fat-eater was the only person to escape In others the only fat-avoider was the only victim I began to see daylight

That these were no mere coincidences soon became apparent, for I found no such coincidences in the opposite direction. Exceptions and discrepancies occurred and often, but I have not yet found a single family where the usual position has been completely reversed—i e, where all the fat-eaters had become casualties and all the fat-shy remained well and healthy. It must be understood that it is a tendency only, although a very strong one The fat-eater has no absolute immunity; the fat-shy are not necessarily doomed, but the probability is always in that direction, and in the long run probabilities will tell Perhaps the best way to put it is this "When several persons are equally exposed to infection, those who habitually eat animal fat will probably escape—but may not, while those who avoid fat may escape—but probably will not"

Some Illustrative Cases

I have investigated more than 40 families fulfilling the conditions I have suggested Space forbids my publishing more than a few records I would assure my readers that all these families were free from tuberculosis (as far as is known) until they were exposed to infection And I would ask them to remember that these records are by no means exceptional—merely striking examples of a general rule

CASE 1 —The family of father, mother, and seven children lived in a five-roomed cottage in a Hampshire village They were exposed to infection by another son who came home in 1920 after war service in Russia and soon after developed a persistent cough, the nature of which was not discovered until one of the daughters had become infected From that time to this there have never been less than two positive cases in that home Here they are as they would appear in the usual family history

Mother, 57, P T pos	Father, 59, alive and well.
Sons	Daughters
Son, 30, alive and well	*Daughter, 21, died P T 1921*
Son, 28, died P T 1922	*Daughter, 17, died P T 1924*
Son, 22, alive and well	*Daughter, 29, P T pos advanced*
* *Son, 11, tub ankle*	
Son, 12, alive and well	

A mere casualty list telling us very little

The son of 28 seems to have been the introducer of infection Put him on one side and divide the rest into fat eaters and fat-shy This is best done by asking the mother, an expert witness on this matter, whose memory rarely fails Put them into parallel columns and a flood of light is thrown upon a very dark situation

FAT EATERS	FAT SHY
Father, 59, alive and well	*Mother, 59, P T pos*
Son, 30, alive and well	*Daughter, 21, died P T 1921*
	Daughter, 17, died P T 1924
	Daughter, 29, P T pos advanced
	* *Son, 11, tub ankle*
	Son, 12, alive and well

The son of 22 is away from home and I could get no reliable history of his fat habits He is almost certainly healthy because he is serving in the Marines

CASE 2 —This family moved into a badly infected house in (I think) 1920 Here is their present condition

FAT EATERS	FAT SHY
Father alive and well	*Mother dying P T*
Son, 18, alive and well	*Boy, 23, died P T 1926*
Daughter, 14, alive and well	*Girl, 18, died P T 1925*
Son, 9, alive and well	*Girl, 17, died P T 1925*
	Boy, 13, early P T
	Girl, 24, alive and well

Exceptions can often be explained by careful inquiries into the domestic details, especially as regards sleeping accommodation In this case the fat-shy girl of 24 who has escaped so far has all along shared a room with the healthy girl of 14 This little bit of shelter may have helped her

---

* Cases of bone and joint tuberculosis are inserted for completeness I doubt if they follow the usual rule, at any rate, with the same frequency.

CASE 3—Infection was by the father, an old-standing positive case

FAT-EATERS	FAT-SHY
Mother 60 alive and well	*Son 25, died P T 1917*
Daughter, 33, alive and well	*Daughter, 25, died P T 1922*
	Daughter 21, died P T 1923
	Son, 20 P T. pos advanced
	Daughter, 35, doubtful.

The daughter of 35 is married and living at a distance. She is said to be "delicate" and has been refused by an insurance company, but possibly on her family history.

Now in these three families there were many of the fat-shy, and so there were many casualties Introducing infection here is like starting a fire in a timber yard There is plenty of inflammable material lying about and too often the conflagration only comes to an end for lack of fuel It is interesting to notice how closely a bad family history is associated with the presence of infection and many fat-shy members Of course, a spotless record may mean nothing more than absence of infection, just as a saint may be greatly indebted to his freedom from temptation But potentially a family of this sort is always weak and their resistance crumples up as soon as severe and continuous infection has to be faced Now, by way of contrast, here are some families where the fat-shy are few.

CASE 4—Infection was by a lodger.

FAT-EATERS.	FAT-SHY
Mother, alive and well	*Boy, 11, early P.T*
Father alive and well.	*Boy, 10, early P T*
Boy, alive and well	
Girl, alive and well	
Girl, alive and well	

CASE 5

FAT-EATERS	FAT-SHY
Father, alive and well	*Boy, 14, P T*
Mother, alive and well.	
Ten children alive and well.	

This family had a floor in a tenement house, and on the floor below lived a consumptive woman. There was little or no intervisiting but they shared a lavatory, and, of course, the stairs and passages were common property With such slight opportunities for infection one might be sure that only a fat-shy person could come to harm And so it turned out

CASE 6 is similar, except that the mother is the infecting agent. The father and eight children were exposed and again the only fat-shy person is singled out in uncanny fashion

FAT-EATERS	FAT-SHY
Father, alive and well	*Boy, 12, P T*
Seven children, alive and well	

That these things are chance common sense forbids I have chosen clear-cut cases for demonstration, of which I have many more but it must not be thought that all histories are clear cut Accidents will happen even to fat-eaters, but it will be found that in nearly every case their percentage of casualties is far below that of the fat-shy

Fat-eaters and Fat-avoiders

The classification is easy enough. We all have a certain liking or disliking for animal fat, which if uncontrolled determines our habits, and a direct question usually brings a direct answer The fat-eater eats all forms of fat, generally because he likes it, sometimes to avoid waste, or bad manners and the like Many prefer fat to lean and eat large quantities of it, but I have never been able to trace in them any advantage over the normal fat-eater The fat-shy sometimes avoid all forms but often make exceptions the common ones being butter, "crisp" (i e overcooked) fat ham and bacon and dripping People who eat a few fats only are clearly fat-shy and must be so classed. They do not eat enough for their protection. Especially is this the case with ham and bacon, which, oddly enough, few of them object to, and which seem to have no protective effect whatever That these fats are deficient in vitamins is suggestive. All the fat-shy agree in their dislike of mutton and beef fat, and from this one might think that these are the important fats for our purpose but clearly it may not be so at all but just that when only a few fats are eaten and the common ones rejected the total amount is too small or taken at too long intervals That everyone can eat fat if he chooses is certain. Of some 300 admissions to Heath End† 80 per cent had avoided fat all their lives Nevertheless, they all ate it "fair and square, as it comes," when the importance of so doing was frankly told them, and I can only recall one case (a hopelessly over-indulged child) where we had any difficulty

A Different Angle

By inquiring among patients at dispensaries and elsewhere I found that the large majority were fat-shy, and further that the infection to which their resistance had yielded was often very slight and occasional whereas the fat-eater seemed to require sudden exposure to many bacilli, usually continuing day after day for months Histories of infection are merely estimations of probabilities and prove nothing, but hearing a good many gave me that impression.

The fat-eater cannot suddenly share a bed with a consumptive, nor plunge into badly infected lodgings nor stand the introduction into his small office of a clerk who coughs incessantly and proceeds to close every possible crack to avoid draughts. But the fat-shy cannot meet an infectious friend once a week at a club, nor teach in a large, airy school-room where an infectious child came for just three days And many of the fat-shy were apparently exposed to quite occasional risk by their occupation Now we have seen the fat-eater exposed to very severe infection in the home and remaining healthy. Home infection is nearly always gradual, the air slowly becoming more and more laden with bacilli Most fat-eaters seem to be infected outside the home where sudden severe exposure is more likely, and it seemed that this element of suddenness was all-important. The fat-eater is apparently immune to moderate doses of bacilli and eventually to very large ones provided that the increase is fairly gradual I made a rough working hypothesis

A Rough Working Hypothesis

We may, I think, regard a family of mixed fat-eaters and fat-shy as patients who are about to have a vaccine treatment and we may think of fat as in some way very helpful if not essential to the formation of antibodies The fat-shy, with their low resistance, must be very cautiously dealt with; a very small initial dose, and carefully increased subsequent doses. In like manner they can inhale a very few bacilli at first and very slowly and gradually deal with more and more

With the fat-eater liberties can be taken His higher resistance allows a bigger initial dose and much less care about the subsequent doses In the same way he can inhale with impunity a comparatively large dose of tubercle bacilli and increase the number much more carelessly Doses which would be fatal to the other are positively beneficial to him helping him to build up an ever-increasing resistance He can stand anything in reason—anything that is, but a series of overwhelming doses to start with. Exceptions to the general rule must occur—it cannot be otherwise—the fat-shy may have very good luck or the fat-eater very bad luck. But it is to the last degree unlikely that all the fat-eaters in a large family would meet with such an extraordinary series of disasters as to break down all their resistances, while at the same time all the fat-shy would have such astonishing luck as to receive exactly the right immunising doses throughout

I tested this theory by applying it to marriage. (*a*) to a person already infectious and (*b*) to a healthy person who afterwards developed pulmonary tuber-

---

† That this is an abnormal percentage is shown by a rough census in the elementary schools of Aldershot among children of about the same ages and the same social class It shows a small majority for the fat-eaters, 950 to 850

and distinguished from other sera Scarlet fever antitoxin protects rabbits against the more acute phase of the septicæmia due to the *streptococcus* Later, many of the protected animals develop arthritis and other manifestations of subacute infection.

(3) The test is a quantitative one, "good" sera can be distinguished from "poor"

(4) In the case of three pairs of antitoxic sera differences were detected by the rabbit test corresponding to differences on human test

(5) The method, if confirmed in further work, may provide a means of titrating scarlet fever antitoxic serum in the laboratory

PULMONARY TUBERCULOSIS

A SIMPLE PREVENTIVE

By W B VAILE, M R C S Eng.,
MEDICAL OFFICER TO THE CHURCH ARMY SANATORIUM FOR BOYS, HEATH END, ALDERSHOT

Seven years ago I began to investigate the incidence of pulmonary tuberculosis in families exposed to infection, trying to find the principle of selection with a view to the prevention of the disease I began by assuming that every case of pulmonary tuberculosis was as certainly the result of infection as every case of measles. Next, that if several persons are equally exposed to the same infection under the same conditions for the same time, their escape or infection must depend on the resistance of the individual And the task I set myself was to find the secret of that resistance

My opportunities have been only those of a country practitioner in charge of a sanatorium for boys with about 40 beds I chose large families (to avoid freak results) and small houses (to ensure fairly equal exposure of each member) It is, of course, impossible that all should inhale the same number of bacilli per breath or per day, but it is sufficient for our purpose that they all live and sleep at home, healthy and infected mingling in the ordinary intercourse of daily life They will all inhale the same strains of bacilli mixed in the same proportions Whether those bacilli are many or few matters not, since everyone must breathe the air in that small home The attack is the same The conditions under which they have to meet it are the same All the countless factors of ventilation, sunlight, good or bad food, cleanliness, careful or careless coughing and spitting, &c, need not be taken into account They were the same for all And the hereditary resistance of the family, or at any rate of the children, may be assumed to be the same Everyone starts fair It is, in fact, a classic race and not a handicap

Search for Some Common Factor

After some years of such a test we need only inquire into the health of each member to know which have the better resistance I wished to find some common factor which all or most of the survivors possessed and all or most of the infected lacked None of the usual ætiological factors seemed to fit, though any one of them would account for a case here and there Nothing was of general application until I began to ask a very simple question—six words only—"Do you eat fat—or not?" I found that most of the healthy survivors had always done so, while the great bulk of the infected, the dead, and the dying had had a lifelong dislike for fat and had avoided it as far as possible all their lives In family after family I found this trivial peculiarity dominating the situation, brushing aside other influences, forming the dividing line between healthy and infected, living and dead In many families all the fat-eaters had escaped, while all the fat-shy (to use a convenient expression) had become infected In some the only fat-eater was the only person to escape In others the only fat-avoider was the only victim I began to see daylight

That these were no mere coincidences soon became apparent, for I found no such coincidences in the opposite direction Exceptions and discrepancies occurred and often, but I have not yet found a single family where the usual position has been completely reversed—i e, where all the fat-eaters had become casualties and all the fat-shy remained well and healthy. *It must be understood that it is a tendency* only, although a very strong one The fat-eater has no absolute immunity, the fat-shy are not necessarily *doomed, but the probability is always in that direction,* and in the long run probabilities will tell Perhaps the best way to put it is this • "When several persons are equally exposed to infection, those who habitually eat animal fat will probably escape—but may not, while those who avoid fat may escape—but probably will not"

Some Illustrative Cases

I have investigated more than 40 families fulfilling the conditions I have suggested Space forbids my publishing more than a few records I would assure my readers that all these families were free from tuberculosis (as far as is known) until they were exposed to infection And I would ask them to remember that these records are by no means exceptional—merely striking examples of a general rule

Case 1 —The family of father, mother, and seven children lived in a five-roomed cottage in a Hampshire village They were exposed *to infection* by another son who came home in 1920 after war service in Russia and soon after developed a persistent cough, the nature of which was not discovered until one of the daughters had become infected From that time to this there have never been less than two positive cases in that home Here they are as they would appear in the usual family history

Mother, 57, P T pos	Father, 59, alive and well
Sons	Daughters
Son, 30, alive and well	*Daughter, 21, died P T 1921*
Son, 28, died P T 1922	*Daughter, 17, died P T 1924*
Son, 22, alive and well	*Daughter, 29, P.T pos advanced*
**Son, 11, tub ankle*	
Son, 12, alive and well	

A mere casualty list telling us very little

The son of 28 seems to have been the introducer of infection *Put him on one side and divide the rest* into fat eaters and fat-shy This is best done by asking the mother, an expert witness on this matter, whose memory rarely fails Put them into parallel columns and a flood of light is thrown upon a very dark situation

Fat-eaters	Fat shy
Father, 59, alive and well	*Mother, 59, P T pos*
Son, 30, alive and well	*Daughter, 21, died P T 1921*
	Daughter, 17, died P T 1924
	Daughter, 29, P T pos advanced
	**Son, 11, tub ankle*
	Son, 12, alive and well

The son of 22 is away from home and I could get no reliable history of his fat habits He is almost certainly healthy because he is serving in the Marines

Case 2 —This family moved into a badly infected house in (I think) 1920 Here is their present condition.

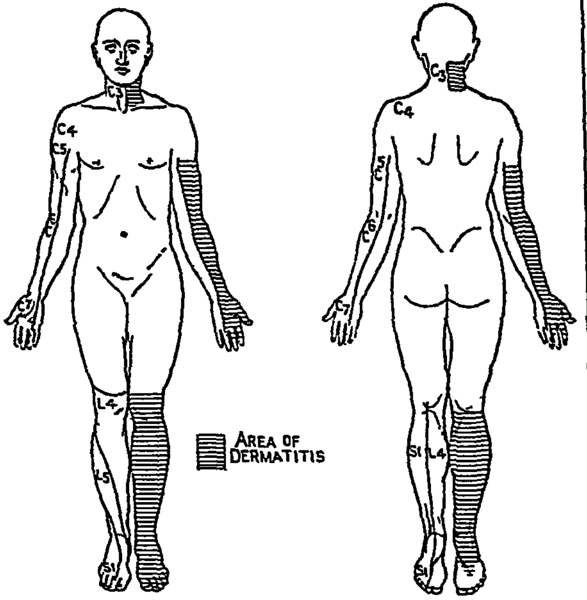
Fat eaters	Fat shy
Father alive and well	*Mother dying P T*
Son, 18, alive and well	*Boy, 23, died P T 1926*
Daughter, 14, alive and well	*Girl, 18, died P T 1925*
Son, 9, alive and well	*Girl, 17, died P T 1925*
	Boy, 13, early P T
	Girl, 24, alive and well

Exceptions can often be explained by careful inquiries into the domestic details, especially as regards sleeping accommodation In this case the fat-shy girl of 24 who has escaped so far has all along shared a room with the healthy girl of 14 This little bit of shelter may have helped her some cases have been seen with well-marked skin signs on the scrotum and buttocks

---

* Cases of bone and joint tuberculosis are inserted for completeness I doubt if they follow the usual rule, at any rate, with the same frequency

Usually, however, the skin lesions were most prominent in the skin supplied by the following nerves —Neck second, third, and fourth cervical, arms. fifth, sixth, and seventh cervical, legs fourth and fifth lumbar and first sacral The distribution of the dermatitis was absolutely symmetrical on both sides of the body



Diagrams showing distribution of the dermatitis, and cutaneous nerves

Resemblances to Myxœdema

From these observations it seems that the toxin of pellagra produces changes in the thyroid gland, leading to an insufficiency of thyroxin being secreted, with the result that pellagra in some respects resembles myxœdema.

Myxœdema	Pellagra
Skin thickened and rough	Skin thickened and rough
Slight œdema sometimes present	Slight œdema
Skin dry and scaly	Skin dry and scaly
Tongue swollen	Tongue sometimes swollen
Mental dullness and apathy	Mental dullness and apathy frequent

Another observer, G A Watson, in the Annual Report of the Board of Control for 1925, mentions a case which was first diagnosed as myxœdema and later developed a typical pellagrous dermatitis and died On post-mortem examination the thyroid gland was found to be practically absent W. Susman, writing in the *Edinburgh Medical Journal*, February, 1926, gives an account of the morbid anatomy and histology of two cases of pellagra, in which the thyroid gland was generally fibrosed. He concludes that the oldest lesion was in the thyroid

Treatment

In my series of cases the administration of thyroid gland tablets (2 gr) daily produced a rapid improvement in these pellagrins, some of whom had very severe skin lesions, the administration of the tablets caused a complete disappearance of the skin trouble in a few days (average about 10 to 15 days), and the patients felt physically improved and seemed mentally improved Out of over 100 pellagrins treated by this method in the year 1924, only eight had any recurrence of the condition during the year 1925 Because in pellagra there is an achlorhydria, the administration of acid hydrochlor dilutum in 5-minim doses three times daily was tried, but the condition of the patients undergoing this treatment remained unaltered Arsenical mixtures did not produce any alteration of the condition, and after observing the results of these three treatments, the thyroid treatment has been adopted as a routine as giving the most favourable results in the cases at the Central Prison, Zomba

Ætiology.

Pellagra is, apparently, due to some obscure toxin, probably microbic or parasitic in origin However, many of the cases in the Central Prison, Zomba, have been subjects of ankylostomiasis or bilharzia or a combination of the two conditions It is known that these two intestinal parasites are capable of producing a profound anæmia, resembling pernicious anæmia, and it is known that in the later stages of pernicious anæmia changes take place in the nervous system which may lead to subacute and combined sclerosis of the cord, therefore it is not difficult to regard the course of pellagra as being due to the following —

1. Infection of the individual with some parasite or micro-organism 2 Formation of a toxin producing · (*a*) changes in thyroid gland, (*b*) anæmia. Forty blood examinations were made, and all cases had a reduction in the number of red cells, varying from 500,000 to 1,000,000 The percentage hæmoglobin varied between 40 and 70, and a marked eosinophilia was present in most cases, (*c*) changes in nervous system leading to peripheral neuritis, melancholia, (*d*) achlorhydria, &c , (*e*) nephritis

From this observation it is apparent that there is in pellagra 1 A deficiency in thyroid secretion 2 A neuritis of certain nerves in preference to others 3 Skin lesions corresponding to the cutaneous distribution of those nerves

The above observations were made during the years 1924 and 1925, when all the prisoners were on a uniform diet, which consisted chiefly of rice or maize meal, with fish or meat, peas, beans, nuts, fresh vegetables and salt, giving an average food value of about 3000 calories per person per diem

In conclusion, I wish to thank Dr F. E Whitehead, Director of the Nyasaland Medical Service, for his permission to publish this article

Clinical and Laboratory Notes.

A CASE OF
HERNIA THROUGH THE TRANSVERSE MESOCOLON

By S T Irwin, M Ch Belf , F R C S Edin ,
SURGEON TO THE ROYAL VICTORIA HOSPITAL, BELFAST

The following case of hernia of the whole small intestine through the transverse mesocolon, following gastro-enterostomy, is, I think, of some rarity

In September, 1926, I was asked to see a woman aged 30 who had had a gastro-enterostomy for gastric ulcer seven years before After the operation the patient had been very ill the main symptom being an extreme degree of vomiting with prostration She made a very slow convalescence and had, indeed, never been quite well since the operation For the last few months she had been suffering from pain associated with diarrhœa almost immediately after food There was no passage of blood by the rectum She could take only a very small quantity of food at a time owing to a feeling of fullness, and though there was little actual vomiting, the patient almost constantly felt sick and had lost a stone and a half in weight About three years ago she had an attack of very severe pain and from that time onwards her sufferings had been accentuated

On examination the patient was pale, drawn, and emaciated The abdomen was retracted and generally tender No mass could be felt and there was no localised point of tenderness Rectal examination was negative. The patient's temperature was normal, but the pulse ran between 100 and 120 X ray examination was recommended, and Dr F P Montgomery reported considerable irregularity and puckering around the mouth of the stoma and extreme hypermotility of the meal, a suggestion was made that a gastrojejunal ulcer might be present. On later examination of the abdomen visible peristalsis in the small intestine was noticed and a provisional diagnosis of obstruction at the seat of a tuberculous ulcer near the lower end of the ileum was made

Operation was advised and was performed on Sept 25th On the abdomen being opened a large mass of distended culosis Of the first class I have no cases of my own Happily they are uncommon now But Sir Herman Weber's series, where nine husbands tuberculous before marriage lost 18 wives, are suggestive It is probable that some of the 18 were fat-eaters and others fat-shy, but all alike became infected

Looking through my small collection of cases of the second class I found that of 34 fat-eaters in this position only one became infected, while of six fat-shy persons four developed the disease

Prevention

We have seen the fat-eater asserting his superiority over his fat-shy brother in different ways from different angles Like the arithmetical hero "A," he wins every contest easily He has a defence good enough for ordinary needs, and if escape is possible he does escape Only when he makes impossible demands upon his resistance does it fail him

That everyone can eat fat is certain and that the fat-eater by choice and the fat-eater by persuasion are equally protected (which has been doubted) the following examples clearly show In each case the circumstances were parallel The father was dying of pulmonary tuberculosis, they were very poor, and the mother tried to persuade her children to eat fat for economy's sake It is evident that the result depends on her firmness and not at all on a natural taste for fat

First we have a total failure The children refused to touch it They hid it under their plates or in their pockets All became infected while the mother, who ate their leavings, escaped

CASE 7

FAT EATER	FAT SHY
Mother, alive and well	*Boy, 15, P T*
	Girl, 16, tub hip
	Boy, 13, P T
	Boy, 12, P T

In CASE 8 the mother ate fat herself and persuaded four out of her five children to do the same I believe that none liked it. The only fat avoider was the only one to show signs

FAT EATERS	FAT SHY
Mother, alive and well	*Boy, 13, P T*
Boy, alive and well	
Boy, alive and well	
Girl, alive and well	
Boy, alive and well	

In CASE 9 the mother was very firm and sensible Most of the children heartily disliked fat, but they did as they were told, and here is the result, six years after the father's death

FAT EATERS	FAT SHY
Mother, alive and well	None
Boy, 19, alive and well	
Girl, 16, alive and well	
Girl, 12, alive and well	
Boy, 11, alive and well	
Boy, 10, alive and well	

In CASE 10 the same result was brought about by a lucky accident The mother hit upon the idea of feeding the whole family on suet pudding, because it was cheap and nourishing It formed their staple food nearly every day She and her nine children all escaped

My own small experience is the same For six years in every home where I have had a case of pulmonary tuberculosis I have strongly advised the mother to insist upon everyone eating fat and to give them liberal and frequent suet I have no failures to record In no home where this has been done have any further cases been brought to my notice

There is, I think, every reason to hope that a wider knowledge of these simple facts among the general public may lead to a great diminution of pulmonary tuberculosis At present we are dependent for our safety on the intelligence and the goodwill of the infectious person We exhort him to protect us Here is a simple way of protecting ourselves, so easily, so effectively, and without the expenditure of an extra halfpenny either by the individual or by the community And if I have been able to help in that direction—why, that is the whole object of this paper

---

OBSERVATIONS ON PELLAGRA IN NYASALAND

BY HORACE M. SHELLEY, M R C S ENG ,
MEDICAL OFFICER, NYASALAND GOVERNMENT

PELLAGRA is not a disease of recent origin, for "Strambio finds that some of the symptoms mentioned in Hippocrates may be those of pellagra" It is actually stated by some that St Francis of Assisi probably suffered from the disease In 1578 the disease was probably known as "Pellarella," but Gaspar Casal, in 1735, was the first to recognise that the gastro-intestinal, cutaneous, and mental symptoms exhibited by the sufferers constituted a clinical entity. In 1872 Lombroso began to study pellagra, and continued to do so until he died in 1909 Sambon commenced his work on the disease in 1905

Pellagra was first discovered to be present in Nyasaland by Stannus in 1910 , its presence was again commented on by Milne-Tough in 1922 Pellagra is prevalent practically all over the world , it occurs in both flat and hilly districts, and the cases are most numerous near moving water

There are three main theories as to the cause of the disease 1 The deficiency theory, which states that pellagra is due to the absence of a nitrogenous complex from the food 2 The maize theory, which states that the disease is produced by eating damaged or diseased maize 3 The parasitic theory, which states that the disease is due to infection with some living organism

Symptoms and Course

In short, the symptoms and signs of pellagra are · 1 Langour and debility, dyspepsia, and diarrhœa 2 Erythema of the face, back, arms, hands, chest, and legs 3 Improvements occur, followed by exacerbations, until, in the course of a few years, cerebro-spinal symptoms develop with paralysis, spastic gait, melancholia 4 Cachexia results The duration of the disease extends to 10, or, perhaps, 15 years

The following data have been obtained from observation of the pellagrins in the Central Prison Hospital, Zomba, and from cases occurring in the general population These data support the following opinions —

1 Pellagra is not a disease confined in Nyasaland solely to prisoners, as was previously thought, but occurs with comparative frequency amongst the general population Natives have actually commenced to undergo their sentences at the Central Prison with the disease already well marked Several cases have occurred in native soldiers of the King's African Rifles, and in the general population

2 Pellagra is not a disease which is caused solely by diet, because if that were so, there is no reason why the cases should not be more numerous in the Central Prison, where all prisoners receive diet of both the same quality and quantity, also, it appears that in certain British asylums the disease has become endemic, and in such every year a number of fresh cases are reported G A Watson, in the Ninth Annual Report of the Board of Control for the Year 1922, describes the outbreak in the Lancashire County Asylum, Rainhill, during the years 1913 to 1922 "From 1913 to 1918 inclusive 36 definite cases were noted, though there were several others of central neuritis with all the features of pellagra except the rash In 1919–20 no further cases were reported, and the survivors of previous years showed no recurrences In 1921 there was only one case, but in 1922 a severe outbreak occurred, 14 new cases being recorded The majority of these had been in the institute for a considerable time, and, therefore, the adequacy of the diet was carefully investigated It was found in 1922, the year of the severe outbreak, the diet was more generous and more varied than it had been in any previous year, even before the war"

3 It would appear that pellagra is a disease due to toxic absorption producing certain changes in the nervous system, leading to a neuritis of certain peripheral nerves This neuritis produces trophic changes in the areas of the skin supplied by these nerves, with the result that the skin becomes dry and scaly from interference with its nutrition These trophic lesions of the skin appear most marked on those parts of the body which are exposed to sunlight, but

lungs and hæmic bruits were heard at both the base and apex of heart The spleen was enlarged and was palpable as a hard mass extending for a hand's breadth below the costal margin All the superficial glands were palpable, but were soft and not greatly enlarged The temperature was 99 4° F , the pulse-rate was 100, and the respiration-rate 25 After suddenly vomiting some blood six hours after admission the patient died The following results were obtained from samples of blood taken before death Percentage of hæmoglobin, 35 , red blood corpuscles, 2,300,000 per c mm , white blood corpuscles, 50,000 97 per cent of the white corpuscles were of the lymphocytic type Poikilocytosis, anisocytosis, and diminution of pigment in the red cells were marked There were neither red cells nor malarial parasites The lymphocytes averaged 10 µ in diameter and were of a premature type, with large ovoid purple nucleus and a complete outer ring of blue protoplasm (Leishman's stain)

Post-mortem examination by Dr W A Young on Sept 28th The lungs were congested but not consolidated The myocardium, pericardium, and endocardium were spotted with petechial hæmorrhages , there was no valvular lesion of the heart The spleen was enlarged, thickened, and congested with dark areas resembling "hæmorrhages" in the medulla The liver was congested and had a fatty appearance The internal glands were not enlarged The kidneys showed hæmorrhages beneath the capsules, which stripped easily The cortex and medulla were clearly defined, the cortex being pale and the medulla dark and striated, with conspicuous red lines There were a few hæmorrhagic spots in the cortices The bone-marrow was uniformly dark red The stomach, when opened, displayed an oozing mucosa and dark black contents There was a hard chancre on the glans penis Sections were made of the liver, kidneys, and spleen, and smears taken from the bone-marrow The bone-marrow smears stained badly but showed a big preponderance of lymphocytes The spleen pulp showed an enormous number of lymphocytes and also thickened trabeculæ and evidence of blood destruction No malarial parasites were seen The liver was fatty and in both this organ and the kidneys there was an infiltration of lymphocytes

The points which arose for consideration were the effect of the intravenous arsenic on the presumably already existing disease, and the possible part played by the *Treponema pallidum* The onset of all the severe terminal symptoms after the injection of novarsenobillon seems to indicate that the drug precipitated death and caused the fatal exacerbation

Our thanks are due to Dr A J R O'Brien, surgical specialist, into whose ward the case was admitted and to the director of medical and sanitary services. Gold Coast, for permission to publish these notes

---

Medical Societies.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A MEETING of this Society was held at Leeds on Dec 17th, when Mr W GOUGH, the President, delivered a valedictory address, after which Dr D DOUGAL (Manchester) described an

Unusual Diffuse Uterine Tumour

The patient was a single woman aged 43, whose main symptom was hæmorrhage, which had been constant for about five months Before this time she had had menorrhagia for about a year She had very little pain A diagnosis of uterine fibroid was made and on Oct 25th, 1926, Dr Dougal removed the uterus subtotally, together with the left appendage , the right ovary was left behind as the patient was very anxious not to have both ovaries removed Recovery was uninterrupted and she was discharged within three weeks

The uterus was enlarged and globular, about the size of a two months' pregnancy, and very hard It was not encapsuled, but had polypoid extensions into the cavity, and Dr. Dougal thought that the tumour was probably an adenomyoma becoming submucous, but on microscopical section no obvious glandular structures were seen This seemed very unusual, but a description of a similar growth, written in 1919 by D B Casler, was later found.

The tumour was in the fundus of the uterus, slightly on the posterior aspect It was a diffuse growth and consisted of fibro muscular trabeculæ, among which were scattered islands of softer tissue These islands projected from the surface on section and gave the tumour a very peculiar appearance The cut surface had not the homogeneous cheesy appearance usually associated with sarcomata, and there was no cystic formation The cavity of the uterus was occupied by a number of polypi pale in colour These again did not suggest sarcoma They consisted of tissue very similar to the endometrial stroma , there were many oval cells closely packed together, and at the inner part there was a good deal of blood extravasation The polypi were covered by a single layer of columnar epithelium and no glands were to be seen None of the cells were definitely of malignant type Lining the unaffected parts of the endometrium the mucous membrane was normal but somewhat compressed, especially as it approached the polypoid formation Further in the uterine wall islands of cellular tissue lay amidst the muscular bundles , here again the cells were of the same type, and there was no necrosis The growth had seemingly pushed in among the muscular bundles and displaced them, or in places had actually destroyed them by compression There were areas where the stromal tissue looked as though it were travelling along veins or lymphatics, but it was doubtful if it had done so Nearer the serous surface some of the cellular spaces had a somewhat different appearance In these, in addition to the ordinary stroma cells there were a few lines of larger cells which appeared to be the remains of broken-down glands

The tumour, said Dr. Dougal, was evidently either a sarcoma or a benign tumour of the endometrial stroma which had grown first into the wall of the uterus and later towards the cavity in the form of polypi Casler's case had been of exactly similar type, and he had considered it to be an endometrioma without glands

The PRESIDENT said that he thought that the tumour was probably an endometrioma —Prof M H. PHILLIPS (Sheffield) said that on first examining the sections he had regarded the growth as a sarcoma, but he had come round to the view that it was an endometrioma —Mr W W KING (Sheffield) said that if endometrial stroma was invading the muscle the tumour should be described as a sarcoma —It was decided to refer the specimen to the Manchester Pathological Subcommittee

Mr King then described two cases of

Concealed Accidental Hæmorrhage

with special reference to the histological condition of the muscle

CASE 1 —A multipara, aged 33, eight months' pregnant, had had abdominal pain and bleeding for a week She presented the typical picture of concealed accidental hæmorrhage , she was pale, she had a rapid pulse, and the uterus was hard and tender There was no urine in the bladder At operation the uterus was plum-coloured from effused blood There was free blood in the peritoneal cavity and large hæmatomata in both broad ligaments Hysterectomy was performed, but the patient died in a few hours from shock

CASE 2 —An unmarried girl, aged 22, was not known to be pregnant until she was taken ill She was thought to be in labour, as the cervix was dilating and there was a little hæmorrhage The uterus was hard, but not tender The pulse-rate was 80, but increased a few hours later Jaundice was noted, and the uterus, though still hard, was not tender A diagnosis of concealed accidental hæmorrhage was made The bladder was empty and no urine had been passed for 12 hours At operation the uterus was plum-coloured and there were large hæmatomata in the broad ligament, but no free blood in the peritoneal cavity Cæsarean section was performed The uterus contracted well, but the patient died an hour later from shock

Histological examination of the uterine muscle in both cases showed that the muscle was quite healthy except for a few small areas which had apparently been cut off by hæmorrhage, and in which the fibres stained badly and the nuclei were indistinct The myometrium was infiltrated with blood and the extravasation was most marked at the inner and outer surface There was no evidence of permeation through the uterine wall, such as might have been expected if the blood had spread outwards from the cavity of the uterus Thrombosed vessels were to be seen In the first case leucocytes were present under the retroplacental hæmorrhage and around some of the vessels They were apparently phagocytic rather than inflammatory in origin

A uterus was also examined which had been removed from a woman who died shortly after an ordinary antepartum hæmorrhage Naked-eye hæmorrhages could easily be seen on the surface and in the muscle The histological appearance was identical with that of the other specimens except that small intestine presented, and it was only with difficulty that its limits could be identified It seemed at first that the small intestine was adherent to the front of the transverse colon Further examination revealed the fact that the whole of the small intestine had passed through the opening in the transverse mesocolon which had been used for the anastomosis It had then passed through a slit in the gastrocolic omentum The opening was comparatively free and the small intestine was easily reduced After the small intestine had been withdrawn the opening in the gastrocolic omentum was closed and the edge of the opening in the transverse mesocolon was sutured to the gastro-enterostomy junction Owing to gross dilatation of the duodenum and the presence of a long loop of jejunum an entero-anastomosis was also done Operation was well borne and convalescence uneventful

At the end of November the patient reported that she had been quite well since the operation, she takes most kinds of food without discomfort, but owing to lack of chewing teeth has avoided red meats The gain in weight has been about one and a half stones

I have only once before seen a hernia through the opening in the transverse mesocolon, and that was in one of the early cases of gastro-enterostomy done in Belfast about 20 years ago This patient died of acute intestinal obstruction. The condition is now rare owing to the universal practice of suturing the transverse mesocolon to the stomach in the neighbourhood of the anastomosis The interest in the present case arises from (1) the extent of the hernia; (2) the difficulty in determining at what stage in the patient's post-operative history the hernia occurred, (3) the fortuitous circumstance which allowed the small intestine to pass forwards through a slit in the gastrocolic omentum, thus preventing an accumulation of small intestine in the lesser sac, (4) the fact that the patient recovered from what under ordinary circumstances would have been a strangulated internal hernia

A CASE OF BRANCHIAL CYST

By J W Thomson, M B, C M Aberd
SURGEON TO CLAYTON HOSPITAL, WAKEFIELD

The following case of branchial cyst presented some unusual features

A man, aged 35, was sent to the ear and throat department of the Wakefield Hospital in July, 1925, with a suggestion that he was suffering from tuberculous disease of the larynx Examination proving negative he was referred to me

History —In July, 1924, he first noticed a swelling in the left side of the neck It gradually increased in size until it became as large as half a cricket ball At this stage he had pain along the alveolar margin under the lobule of the ear and under the left shoulder, and headache The swelling and pain disappeared after a sudden discharge from the mouth of a yellowish jelly-like substance There were several such occurrences between this date and the end of the year In January, 1925, the swelling was associated with huskiness of the voice In March, 1925, he became an out-patient at another institution, from which it has been ascertained that there was fixation of the left vocal cord and that X ray examination of the chest for tuberculous disease was negative His condition continued to deteriorate The intervals between the attacks became shorter, the discharge was redder, the pain was more severe, and, when the swelling was at its height, dysphagia, dyspnœa, and aphonia completed the picture of misery

Examination —The patient was pale and thin and dejected and his voice was hoarse There was a somewhat tense swelling the size of a tangerine orange on the left side of the neck about the level of the upper border of the thyroid cartilage The skin was not involved and the swelling was not translucent There was fluctuation and the outer border was overlapped by the sternomastoid muscle

Diagnosis —Whilst branchial cysts must be differentiated from tuberculous glands, cystic hygromata and several other conditions, the history of this case made it probable that this was a branchial cyst

Operation —The cyst had ruptured on the previous day just before admission to hospital so that it was not possible to obtain a specimen of the fluid, and the outline of the neck was normal, showing no trace of any swelling An ample transverse incision revealed a flaccid sac under the deep fascia It was easily freed from the sternomastoid and the great vessels, and as it passed inwards it was detached from the left lamella of the larynx and the greater cornu of the hyoid bone From these attachments the narrowing sac passed backwards and inwards to the lateral wall of the pharynx The opening into the pharynx admitted the index-finger The dissection here became difficult, owing to the depth of the wound and the firm attachment of the cyst to surrounding structures, and somewhat dangerous from proximity to the larynx, and I was not satisfied with its thoroughness The cyst did not pass between the external and internal carotids, nor did it appear to thin the sterno mastoid The wound was packed and the following day some of the packing appeared in the pharynx Subsequently a tampon drain was used The patient was discharged on August 12th, 1925 Two months afterwards he was alert and vigorous and could, by some manipulation of the cervical muscle, express from the wound a drop or two of sero purulent fluid His voice had lost its hoarseness December, 1926 the external wound is healed and there is no swelling He is in good health, but there is still some slight discharge of fluid from the mouth at varying intervals

Pathological Report —The epithelial lining is very irregular both as regards the appearance of the cells and the number of layers of cells The number of layers varies from four or five more or less cylindrical cells, particularly where the cyst wall is much folded, to only one layer of cubical cells in other places In many places the epithelium is not well defined from the underlying tissue The wall is composed of fibrous tissue for the most part very loose in structure and containing many blood-vessels This tissue on the outer side penetrates irregularly among the surrounding muscle-fibres, so that there is no definite outer limit to the cyst There are one or two small collections of lymphoid tissue present

Discussion.

According to E Wyllis Andrews[1] there are five forms of branchial cysts or fistulæ (1) Complete branchial fistulæ with outer and inner openings (2) Incomplete external fistulæ with outer openings only (3) Incomplete internal fistulæ with inner openings only (4) Branchial cysts with no inner or outer opening (5) Branchial dermoids This case does not quite conform to any of these Any portion of the cleft may be obliterated in such a manner as to form a cyst, or it may become obliterated at several sites, thus forming several cysts[2]

Branchial cysts, which are situated near the skin, are lined with squamous epithelium and are of the nature of dermoid cysts They contain an opaque fluid of striking similarity to tuberculous pus and microscopically they are found to contain cholesterol and squamous epithelium cells[3] If deeply placed the cysts are lined with cylindrical cells and contain a glairy mucoid fluid The latter seldom give rise to symptoms

A CASE OF
ACUTE LEUKÆMIA COMPLICATED BY SYPHILIS

By A J Hawe, M B Liverp, D T M & H,
M R C S Eng,
AND
F S Paterson, M B Edin, D T M Liverp,
MEDICAL OFFICERS, WEST AFRICAN MEDICAL STAFF

The following case presents some points of interest The association of lymphatic leukæmia with recently acquired syphilis, and the rapidly fatal exacerbation of symptoms after treatment with intravenous arsenic, are of unusual occurrence The diagnosis, which was made some hours before the patient's death, was verified by post-mortem examination

The patient, a male African, aged 34, was being treated for syphilis in the out-patient department of the Gold Coast Hospital He attended the hospital with early syphilis on Sept 14th, 1926, and received 0 3 g of novarsenobillon intravenously He returned 13 days later very ill and suffering from advanced anæmia, and asserted that all his symptoms dated from the injection of N A B

Examination showed him to be profoundly anæmic, with blanched mucous membranes and bleeding gums, and very dyspnœic There was advanced pyorrhœa alveolaris and the gums oozed blood and a little pus The tongue was covered with a brown fur Both eyes were discoloured with sub-conjunctival hæmorrhages and some jaundice was discovered on close examination Moist sounds were audible in both fibroid of the lower pole of the uterus or to a non-pregnant horn of a bicornuate uterus

[1] Keen's Surgery, iii, 278 [2] Bickham's Operative Surg iii, 699
[3] Hamilton Bailey British Journal of Surgery, 1922–23, x, 56.

At the Cæsarean section which was immediately performed the lower uterine segment was found stretched over the lower pole of the fœtus, removal of which allowed elevation of the uterus including the intrapelvic portion which was non-adherent and easily released, being held down by a prominent sacral promontory The appearance of the uterus at this stage was bicornuate, the left cornu, which contained the placenta, was found to be that portion of the uterus which was incarcerated in the pelvis After the organ had been manipulated to secure good contraction, the dividing ridge gradually disappeared and all trace of the bicornuate appearance was lost before the abdomen was closed

In this case, said Dr. Lochrane, it was the rather less distensible part of the uterine wall, comprising the site of placental attachment, which had been incarcerated or sacculated Without being able to give any figures he was under the impression that a similar observation had been made by others, and this suggested one possible explanation of this form of partial incarceration of the uterus.

Dr H A Lavelle reported a case of

Rupture of the Bladder followed by Vesico-vaginal Fistula

The patient, aged 34, was a 2-para 32 weeks pregnant, and was admitted to hospital on Dec 31st, 1925, following an unsuccessful delivery with forceps Examination revealed laceration of the vaginal walls with evidence of injury to the bladder, 2 oz of blood being drawn off by catheter A large hydrocephalic head partially fixed in the brim was palpated, craniotomy was done, and the fœtus was easily delivered After operation the patient suffered from incontinence of urine, diarrhœa, and signs of lower abdominal peritonitis accompanied by a pelvic swelling The temperature remained normal until the seventeenth day after admission On the twenty-first day the swelling, which then reached to the level of the umbilicus, disappeared, following the discharge of 4–5 pints of foul-smelling pus per vaginam Except for incontinence of urine the patient made an uninterrupted recovery, but she was readmitted a month ago for the closure of a vesico-vaginal fistula ¾ in from the cervix

The abdominal swelling, said Dr Lavelle, was undoubtedly due to extraperitoneal extravasation of urine, and it was interesting that this should occur in the presence of a vesico-vaginal opening He thought it probable that the fistula dated from the sudden discharge of pus and that the incontinence previous to this was due to failure of the sphincter

Dr Lavelle also described a case of inversion of uterus

Dr Elizabeth Ashby reported a case of rupture of the lower uterine segment during Cæsarean section and a case of fits during pregnancy

A discussion followed in which the President, Mr C E Purslow, Mr Maslen Jones, Mr A M Webber, and Mr A B Danby took part

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH

Blood Pressure

On Dec 14th Prof Murray Lyon reviewed first the factors influencing the blood pressure and showed how the pressure may be altered by the viscosity of the blood, by posture and by mental excitement, muscular effort, and digestion The effects of these also vary, he pointed out, according to the acceleration or slowing of the heart-beat Discussing unduly low blood pressure, Prof Lyon instanced cases of histamine poisoning with peripheral dilatation and loss of blood fluid, which give, he said, a clue to treatment, which should be by transfusion with sugar, saline, or gum solution, the aim being to increase the volume of the blood It is noteworthy that a high blood pressure may be coexistent with a failing heart The question whether it is advisable to attempt to reduce a high pressure he answered by saying that probably an attempt to do so should be made in most cases; results will show whether it is wise to go on with the treatment Prof Lyon emphasised the importance of physical and mental rest, which should be as complete as possible, in the over-stout and flabby, however, the value of graduated exercise is not to be overlooked As regards diet, the danger seems to lie not so much in an excess of protein as in overeating generally A salt-poor or salt-free diet appears useful in some cases He drew attention to the benefit to be derived from venesection, the removal of 3–20 oz. of blood being followed by a fall of pressure which persists Discussing the influence of drugs, he suggested that the almost mysterious effects of potassium iodide may be due to a power to reduce the viscosity of the blood Experimentally, he said, the action of tissue extracts is undoubted, but it has still to be confirmed clinically

LIVERPOOL MEDICAL INSTITUTION

A meeting of this Institution was held on Dec 16th, when Prof R E Kelly read a paper on the

Surgery of the Common Bile-duct,

based on records of 50 cases in which the common duct was explored Amongst conclusions drawn from these, he said, were (1) that the common duct may be packed with stones without jaundice, and even without pain, (2) that stones may be found in the common duct when the gall-bladder is enlarged, (3) that malignant disease may be associated with attacks of pain and a variation in the depth of the jaundice; (4) that stones may be associated with deepening jaundice and no pain ; and (5) that malignant disease and stones may be associated Mere palpation of the common duct was insufficient to give accurate information of the condition of the duct or its contents Every dilated common duct should be explored with the finger, probe, or catheter, and failure to reach the duodenum by these means should be followed by a transduodenal choledochotomy Prof Kelly discussed the difficulty of distinguishing malignant disease from impacted stones in the ampulla of Vater, and said that he thought that malignant disease in this situation was very malignant, and that cures were sometimes due to mistaken diagnosis As regards the details of operation he had used all the incisions recommended, and for particular reasons liked them all He thought, however, that in very obese patients who had a wide costal angle the complete transverse incision gave wonderful access and a strong scar On many occasions he had used the double catheter, one was placed upwards into the hepatic duct and the other down into the duodenum, and the latter served for liquid nourishment

Dr Wallace Jones read a paper on

Vital Capacity in Heart Disease

In his experiments, he said, he had used a simple water spirometer, the readings being expressed as percentages of the standard normal vital capacity calculated by West's formula Fifty normal men and 50 normal women were examined to see how closely the actual vital capacity corresponded with the calculated vital capacity The result showed that though marked individual variation occurred, the average figure was very close to the calculated normal In organic cardiac disease there was a marked fall in the reading, the average being between 50 per cent and 60 per cent of the normal figure The vital capacity was lowest in the mitral stenosis group, especially when mitral stenosis was associated with auricular fibrillation In functional cardiac disease the average reading was 85 per cent, a very high figure in view of the marked dyspnœa generally associated with this condition A group of cases was also kept under observation for a considerable time, and though the vital capacity improved with increase in the cardiac reserve power, the readings only followed slowly the changes in the condition of the heart it was possible to demonstrate the actual rupture of a vein This appeared to show, said Mr. King, that there was serious mechanical obstruction to the venous flow The whole picture of the uteri, both to the naked eye and histologically, suggested the occlusion of the large vessels rather than a permeation of the blood through them as a result of damage to their endothelial lining Young had noted the same fact, and postulated an intravascular clotting from some unknown cause Morse explained the appearance of the uterus upon a theory of torsion of the whole uterus, and Pollock and others had noted extreme torsion of the uterus from left to right Torsion of myomatous uteri was well known to occur, so that there was nothing impossible in a theory of torsion of the pregnant uterus The greatest difficulty in accepting this explanation was the frequency of albuminuria at the time of hæmorrhage There was no sufficient evidence that albuminuria often preceded accidental hæmorrhage, so it could not be causal The condition was generally considered to be a manifestation of toxæmia, but if so it was different, as Whitridge Williams had said, from any of the ordinary types of pregnancy toxæmia Young stated that he considered that the albuminuria was only the result of the autolysis of the separated placenta, but his theory was as yet unproved Hofbauer had produced evidence in favour of histamine as the causative factor, and had reproduced in guinea-pigs the phenomena of concealed accidental hæmorrhage by causing acute histamine poisoning The correct treatment was intimately bound up with the condition of the uterine muscle Hysterectomy had been advocated because the muscle was supposed to be diseased, but it had now been histologically proved that it was not, and clinically it was well recognised that it had not lost its contractile powers and that repeated pregnancies were possible and safe Save in exceptional cases there was, therefore, no justification for Cæsarean section in these cases G FitzGibbon had treated some cases of concealed accidental hæmorrhage with success by palliative measures, and this appeared to be rational It was irrational to operate upon a woman in profound shock without any clearly defined reason, as had been done in the past

Prof FLETCHER SHAW (Manchester) said that Mr King had cited the figures of a number of maternity hospitals, showing that albuminuria only occurred in about 30 per cent of the cases of accidental hæmorrhage, and had quoted Whitridge Williams as giving the figure as 26 per cent These figures he disagreed with, and thought the mistake arose from the difficulty in making a diagnosis of accidental hæmorrhage When a patient, far advanced in pregnancy, was brought into a maternity hospital suffering from hæmorrhage the case was diagnosed as one of placenta prævia if the placenta could be felt, and in other cases the diagnosis of accidental hæmorrhage was made The cases of accidental hæmorrhage thus diagnosed fell into two main clinical groups In one of them the symptoms were comparatively slight, especially the symptom of shock, this group contained the great bulk of these patients, and he felt sure the large majority of them were really cases of marginal placenta prævia The treatment of these cases was very simple, as practically all the patients recovered if the membranes were ruptured and ergot or pituitrin was administered, or if—as was done by the Dublin School—the vagina was tightly packed The other clinical group contained a comparatively small number of cases, but here the patient suffered severely from shock and signs of hæmorrhage These were the patients in whom treatment was not always satisfactory These were definitely cases of accidental hæmorrhage, and in his experience every one of them had albuminuria It was quite possible there might be some other factor along with the toxæmia as a causative agent of the condition, but he felt sure the toxæmia was always present As another proof that the condition was due to a general cause such as a toxæmia, he mentioned the fact that in all these severe cases there were large hæmatomata formed outside the uterus, and the condition must therefore be looked upon as general, and not as due to a merely local cause affecting the uterus alone These severe cases of accidental hæmorrhage formed one of the most serious groups met with in obstetrical practice, and no matter what was done there was a large mortality If the vagina was packed or the membranes ruptured and pituitrin or ergot administered a few of these cases failed to respond, and the patient died of hæmorrhage before the child was born, or, if the uterus was emptied, from post-partum hæmorrhage The cases referred to were very few, but he felt that when they were met with the best treatment was Cæsarean section followed by hysterectomy He himself had treated six such cases in a period of three years during the war, and had saved half of them, but it was evident that they were very uncommon from the fact that since that time he had not met a single case in which he felt called upon to do an abdominal section

Dr J E STACEY (Sheffield) gave figures on ante partum hæmorrhage, from which he concluded that in both accidental hæmorrhage and placenta prævia the cause was toxæmia —The PRESIDENT said that he thought that the treatment should be palliative in every case

Mr A. GOUGH showed a specimen of parasitic myoma removed from a patient aged 42 A pedunculated fibroid the size of a fœtal head had its vascular supply cut off by torsion of its narrow uterine pedicle, At the opposite pole it had adhered to a loop of small intestine, and there was a free supply of blood through the adhesions The tumour was easily separated and the patient did well

---

MIDLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A MEETING of this Society was held at Derby on Dec 14th, Mr FURNEAUX JORDAN (Birmingham), the President, in the chair

Dr C D LOCHRANE reported two cases of

Dystocia

CASE 1 —*The patient was an 8-para*, all her children had been full time and healthy, and she had had no miscarriages The case was seen in consultation on June 1st, 1925, when Dr Lochrane found that the head of the fœtus was born, but the trunk could not be delivered on account of a firm irregular mass obstructing the upper half of the pelvis Previously there had been a slight antepartum hæmorrhage, and although the pains had been strong, the head had only descended to its present position after the mass had been pushed aside

As moderate traction failed to bring about progress in delivery, the patient was deeply anæsthetised with chloroform and morphia, and after considerable difficulty the mass was pushed up and manipulated above the brim of the pelvis This allowed the shoulders and the remainder of a well-developed 10 lb fœtus to be delivered without great difficulty The fœtus showed no œdema or other external abnormality Half an hour later a huge, thick, solid placenta was delivered, it was not markedly œdematous, but weighed 3 lb 3 oz Microscopically the placental tissue was found to be unduly dense in consistence no spirochætes were found

Dr Lochrane said that he had never heard of another case of dystocia from this cause The clinical and pathological picture did not support the view that œdema from albuminuria was a predominating factor in the production of this huge organ, neither was there any suggestion of syphilis, although, unfortunately, blood had not been examined by the Wassermann reaction

CASE 2 —The patient, a primipara aged 23 was admitted to hospital on March 7th, *1926, with a history* of having been in labour 40 hours Her temperature was 98 6° F, her pulse-rate 86, and her general condition good The uterus was found to be unduly prominent and in state approximating to a tonic contraction, the presentation was by the breech, and the fœtal heart-rate was 111 The os was two fingers-breadth dilated and was displaced upwards A cystic mass, the size of a Jaffa orange and continuous with the uterus, occupied the pouch of Douglas The obstruction of labour was regarded as due either to a soft by suggesting a perspective and stimulating ideas It is attractively written and is embellished with five portraits illustrative of the argument

HYSTERIA

By ERNST KRETSCHMER, M D , Professor of Neurology and Psychiatry in Tubingen Authorised English translation by OSWALD H BOLTZ, M D , Senior Assistant Physician in the Manhattan State Hospital, New York City New York and Washington Nervous and Mental Disease Publishing Company 1926 Pp 120

THE approach to the problems of hysteria has within recent years been oriented almost entirely from the viewpoint that its phenomena represent a type of psychogenic reaction According to many this reaction is based on the existence of a prepared subsoil, latent in all, so that all are potential hysterics , others regard the hysterical syndrome as the expression of a certain purpose (half hidden or altogether concealed), a kind of " flight into sickness," of " gain through sickness " The aim of the author is to amalgamate these two seemingly divergent conceptions by endeavouring to show that the hysterical type of psychogenic reaction consists in the development of a tendency to dissimulation and in the use made by the latter of reflex, instinctive, or otherwise biologically preformed mechanisms This view is developed with ingenuity and plausibility, and is satisfying in the sense that it endeavours in some degree to account for the physiological peculiarities of the psychoneurosis, a feature of the condition which seems to impress neurologists more than psychologists No explanation can make any pretence to finality unless it takes these peculiarities into consideration Dr Kretschmer's monograph deserves to be studied by all who are interested in the problems of hysteria

LYMPHOCYTES

The Lymphocyte in Resistance to Tissue-Grafting Malignant Disease and Tuberculous Infection An Experimental Study By JAMES B MURPHY, M D New York Monographs of the Rockefeller Institute for Medical Research No 21 1926 Pp. 168 $2

DURING the past 14 years Dr Murphy and his collaborators have published a large number of papers—over 60, as he states in the introduction to this monograph—in which he has tried to establish by a great variety of experiments that the resistance of the organism to the growth of a malignant tumour resides in the lymphocytes According to him a diminution in the lymphocytes diminishes the resistance, while an increase raises the resistance, and this applies not only to the growth of transplanted tumours, but also to that of spontaneous tumours

The practical and theoretical importance of this contention is obvious Accordingly the earlier experiments of Dr Murphy, on which his conception was based, have been repeated by several observers (Stevenson, Sittenfield, Prime),[1] who completely failed to confirm his experimental observations In subsequent papers Dr Murphy has taken the unusual course of ignoring these criticisms and of putting forward new, though less conclusive, evidence in support of his contention In one of these experiments, which attracted some attention, he claimed to have shown that in a mouse an area of skin, if exposed to an erythema dose of X rays, became resistant to the inoculation of a transplantable tumour if the tumour was implanted *intracutaneously*, while *subcutaneous* transplantation under the same area resulted in the growth of a tumour Although the placing of a piece of tumour into the intracutaneous connective tissue of so delicate a structure as the skin of a mouse so as to avoid the subcutaneous connective tissue is a matter of great technical difficulty, no details were given to show how this could be accomplished A few low-power microphotographs would have furnished evidence in support of the author's contentions that he had succeeded in restricting the implant to the cutis, but the only figure published gives no indication of the site of the inoculation. In view of these doubts, Dr Murphy's work has not met with general acceptance and has not found the clinical application of which it is obviously capable

The present monograph is not a collection of reprints The author has taken his published observations and " brought them together in a logical fashion in the form of a general summary for the convenience of the reader " This has involved a rewriting of the whole matter The restatement of experimental results, the correctness of which has been questioned, without a reference to the published work of critics, is misleading to those readers who are not fully acquainted with the literature, while to those who are, it must deepen the doubts which they have entertained On the problem itself, whether the lymphocyte represents a mechanism of defence against the growth of cancer, the verdict must be, under the circumstances, " not proven "

HEART AFFECTIONS

Principles of Diagnosis and Treatment in Heart Affections Third edition By Sir JAMES MACKENZIE, M D , F R S , &c , St Andrew's Institute for Clinical Research , and JAMES ORR, M B , Ch B , Physician to the Institute London Humphrey Milford 1926 Pp 242 10s 6d.

THE third edition of the " Principles " is edited by Dr James Orr, who collaborated with Sir James Mackenzie in the previous edition Many sections have been rewritten, and much new matter added, in order to incorporate the more recent theories developed by the late author and his associates at the St Andrew's Institute for Clinical Research Whether the work has gained or lost in value by these changes, must remain a matter of opinion To simplify knowledge, by searching for fundamental principles, is admittedly the object of science, but such principles can only be evolved very gradually, and there is always a danger in attempting to apply them prematurely This danger is illustrated by the chapter on auricular flutter, where the generally accepted explanation of this condition—namely, circus movement—appears to be rejected by the author, not because the experimental evidence is unsound, but because such a hypothesis fails to conform with the " law " that activity of an organ depends on certain regulating structures Surely the " law " should be made to fit the facts, and not the facts the " law "

In previous editions of this book the subject matter consisted primarily of a simple record of careful clinical observations , it is probable that the reader who owing to limitations of time, is compelled to confine his attention to a small book on a large subject is in search of facts rather than theories But disciples of the late Sir James Mackenzie doubtless feel it to be a pious duty to act as guides to the path which their master was exploring at the time of his death, and practitioners who have derived practical help from previous editions may now be willing to take an excursion into more obscure realms

PEDIATRICS

Clinical Pediatrics Edited by R S HAYNES, M D , Clinical Professor of Diseases of Children, Columbia University, New York Vols I -V. London and New York D Appleton and Co. 1926 16s per volume

THE first five volumes of Prof Haynes's system of pediatrics give promise that the completed work will occupy a prominent position in medical literature The aim of the editor is to provide the practitioner with a series of readable monographs on the various phases of children's disease, presented, as far as possible, from the clinical standpoint, and with direct relation to treatment This aim has been most successfully carried out in the volumes which have so far appeared Vol I , by Dr R W Lobenstine and

Reviews and Notices of Books.

THÉRAPEUTIQUE CHIRURGICALE

By P LECÈNE, Professor of Surgery in the University of Paris; and R LERICHE, Professor of Surgery in the University of Strasbourg Vol I Pp 644 Vol II ,with the assistance of F. LEMAITRE Pp 507 Paris Masson et Cie 1926 10s each volume

THESE two volumes, together with the third, which has already been reviewed in these columns, provide a surgical treatise of original type The point of view of the authors is refreshingly new in a surgical work, in that they emphasise the essentially intellectual nature of a therapeutic decision To them, assuming a knowledge of pathology, an ability to formulate a correct diagnosis and the memory of past experience, the determination of the best course to pursue is an affair of the mind alone The book is built upon this supposition A disease is classified according to its therapeutic indications, the different methods of treatment which have been employed are described in principle, the published evidence in favour of one or the other brought forward and criticised in the light of the authors' wide experience, and recommendations are made This mental attitude towards surgical problems is not so prevalent as could be wished, though it is perhaps open to argument whether it is possible or even desirable for the operating surgeon to be so detached since on his mastery of certain details of technique may depend the decision as to the appropriate treatment in a given case Surgery is a handicraft and an art as well as a science However, such a scholarly exposition of the principles of surgical therapeutics as is outlined in this book is of value to any surgeon

Vol I on general surgery and that of the extremities is written solely by Leriche, who preserves an even balance in all his opinions Such questions as the advisability of operating in the presence of shock illustrate this very well He recommends operating to prevent shock before its onset, but never in its presence, unless it be to stanch a bleeding vessel or to repair a single injury of an extremity Transfusion of blood in shock he believes to be valueless The treatment of contaminated wounds is considered in a characteristically logical way He is against any operation in myositis ossificans, except in rare cases after a very long wait for resorption to occur In the section on nerve injuries much useful knowledge has been collected The insistence on the necessity in nerve suture of successive paring of the upper end, until healthy nerve fibrils are met, is sound advice Contrary to our experience, he believes autogenous nerve-grafts to be successful in 35 per cent of cases The treatment of that very troublesome condition causalgia, is, in succession, periarterial sympathectomy, resection of nerves and resection of the posterior roots In sarcoma of the bones X rays are said to be useful when the growth is of the round-celled type, useless when it is of the fusiform type, and in any case to have no effect upon the occurrence of metastases Much pleasure and profit are to be derived from this volume, even when, as in the copy sent for review, it is incorrectly made up, some of the section on the surgery of the upper extremity being missing

In Vol II Lecene writes about diseases of the head and neck, chest and breast, whilst Leriche deals with the spine and pelvis, and Lemaitre with oto-rhino-laryngology This volume is just as satisfactory as the first There is abundant evidence of extensive literary research and personal experience The chapter on the treatment of head injuries makes this difficult subject appear almost simple The value of lumbar puncture is insisted upon, but the accurate information afforded by a spinal manometer seems to have been overlooked In regard to tumours of the brain, the writer points out that the removable ones amount to less than one-third of the total, though he does not neglect to mention the work done by Cushing and by Dandy in the removal of gliomata On the question of exophthalmic goitre he adopts a very sane point of view He says in effect, that as yet there are no comparable series of operated and medically treated patients which can give us actual and reliable information as to the value of surgical treatment He believes it established that one-half the patients recover by medical measures alone, that surgery gives 40 per cent of cures (possibly more) expeditiously, and that sympathectomy is useless X rays being without risk, he recommends them for trial The discussion on cancer of the tongue is also of interest All methods are reviewed, and the opinion is expressed that treatment in the future may resolve itself into radium for the tongue and surgery for the neck He believes the improvement in results lies in the hands of the dentists, who see these lesions much earlier than the surgeons do

This treatise will be read with advantage by any active surgeon The wide experience of the authors coupled with extensive study and a logical exposition of the problems to be faced, with definite conclusions wherever knowledge is complete enough to warrant such judgments, render the book of unusual value There are no illustrations

---

PERNICIOUS ANÆMIA

By F A EVANS M D London Bailliere, Tindall and Cox 1926 Pp 177 11s 6d

APART from statistics of the experience of pernicious anæmia at Johns Hopkins Hospital, there is not much in this book which will not be found in the larger systematic text-books Ætiology, symptoms and treatment are dealt with fairly fully, the anatomy and histology of the blood and organs quite summarily, there is no account of the metabolism of iron We should have welcomed also some more ample discussion of the nature and pathogenesis of the disease It is still unknown whether the changes in the red cells are the cause or the result of the excessive hæmolysis Dr Evans is impressed by the importance of cholesterin and its variations, facts which are in harmony with the view, suggested by the age-incidence, the inevitable fatality and the histological changes, that the disease is essentially a malignant tumour of red corpuscles However, the book is evidently meant less for the pathologist than for the clinician, who may find it useful

---

TYPES OF MIND AND BODY

By E MILLER, M A Camb, M B, M R C S, D P M, Neurologist to the Ministry of Pensions, Clinical Psychologist to West End Hospital for Nervous Diseases London Kegan Paul, Trench, Trubner and Co Ltd 1926 Pp 132 2s 6d

Dr Miller, following Kretschmer, distinguishes two main types of bodily architecture, the "pyknic" (massive and compact) and the "asthenic" (lean and angular) On the psychological plane these types find their correlates, respectively, in the "cyclothymic" and the "schizothymic," the essential difference here being in respect of emotional orientation This appears to resemble closely the extro-introvert classification of Jung, and the distinction is an important one for psychopathology, though of limited usefulness as a type formula when applied to more or less normal individuals Space is found in this small book for a useful account of the results of recent research on the endocrine glands and their neural connexions The author holds that this "endocrinic-vegetative" system provides a medium for the interaction of psychical processes and bodily structure, and suggests that constitutional idiosyncrasy of this part of the organism may be the foundation-stone of type

No reader could expect to find a complete guide to the diversity of human personality in a small volume such as this, but Dr Miller's book will repay perusal

THE LANCET.

NDON: SATURDAY, JANUARY 8, 1927.

NEUROLOGICAL SURGERY

formation and inauguration of a Society of Neurological Surgeons is a sign of the times rely limited in numbers as the exponents of rticular branch of surgery must be, if only e in comparison with other surgical conditions clinical material is somewhat restricted, they ute nevertheless a professional coterie of some ance and importance, and are animated, we el sure, with a spirit of scientific hopefulness ARLES BALLANCE has been elected the first nt of the Society, which has honoured itself ring as honorary members SIR DAVID FERRIER, DWARD SHARPEY-SCHAFER, SIR CHARLES INGTON, SIR ARTHUR KEITH, and Prof G SMITH America has already forestalled this ting development by the founding of a Society ro-Surgeons (it is matter for minor congratula- iat our British colleagues have avoided the n of this needlessly contracted neologism for wn description), and, as is known, there have various countries and at various times promi- ponents of the surgery of the nervous system, s, indeed, in what has now come to take a ed place among the specialties These, r, as is also known, were not infrequently ed by circumstances to "play a lone hand," r names and memories, which in some instances ne readily to the mind are all that remain, potent to inspire their successors, now usefully ed in a company of experts whose future ions will be followed with interest and instruc- iot a few in the more general ranks of surgery ent, comparatively speaking, has been the tion of attack on conditions of the nervous amenable to surgical intervention, that the of some still fortunately with us covers ly the whole period within which such efforts ne *to be regarded as definitely* comprisable ope of surgical procedure It is true, no doubt, more obvious pathological states of depressed racture, rupture of meningeal vessels, and so re handled by "surgeons" as early as medical begins and that for less certainly diagnosed is resort was made to trepanning by members oth with and without any pretence to civilisa- imes long past, as well as in the darker corners eth to-day, but there can equally be *no* doubt era of promise in respect of scientific neuro- urgery was entered on only *when the* experi- showed the way by his investigations into physiology of the lower animals, and when rches of the neuro anatomist finally elucidated ate structure of the neuraxis and its append- ius it is natural and just that the honorary of the new Society should consist of very hed anatomists and physiologists, not only the cardinal rôle they have played in render- le the appearance of the Society in the time but also because their nominal associa- it will prove a constant reminder to its mbers of the fundamental basis of all successful surgery—viz, knowledge of the anatomy and physiology of the mechanisms with which they deal Some may suppose the day will pass when the neurological surgeon will be content to have his clinical diagnoses made for him by neurological physicians, with one or two notable exceptions, such has been the relationship more or less tacitly acquiesced in by those who have regarded themselves as competent to operate in nervous cases Yet under a considerable variety of circumstances collaboration of physician and surgeon still remains desirable if not always essential, and in respect of the nervous system accuracy in topographical diagnosis is an indispensable preliminary to surgical success Hence the surgeon either ought himself to have had a training in neurology or should be prepared to utilise the aid which the neurologist can give him Be this as it may, it is unquestionably for the ultimate benefit of mankind that surgery should persistently insinuate itself into a region which has been explored in little more than its confines The spectre of ' inaccessibility " has often handicapped well-intentioned if less well-directed efforts, but with slow and steady steps the range of feasible interference is being extended Of no less importance is operative security for the patient, and if for some cerebral operations mortality percentages are still high, surgery is but experiencing in this field the hard schooling it has had in others ere increase of knowledge has widened the margins of safety A further equally important aspect of neurological surgery concerns the attainment of adequate degrees of functional recovery after operation Herein, we believe, would lie one of the major advantages to be expected at the surgeon's hands, if only the possibility could be relied on with some little confidence, but too often have technical surgical successes been unaccompanied by functional restitution, largely owing to the peculiar compactness of the structures forming the nervous system, whose physiological value is out of all proportion to their mass Delicacy of touch and nicety of manipulation are here as requisite and will repay the surgeon's skill as greatly as in the case of the eye or the ear To conserve function is an aim no less worthy of his concentrated effort than to remove the results of disease

A wide field lies open before this new Society for theoretical and practical study We felicitate its members on their realisation of the advantages of corporate existence, and believe its installation will usher in a period of enhanced knowledge of the functions of the nervous system and of ever more successful treatment of the serious diseased states with which it is the province of the surgeon to deal

◆

THE ALLEGED INCREASE OF CANCER

IN all European countries except one the recorded mortality from cancer has shown a rapid increase during the last 40 years The one exception is Switzerland, which by 1880 had the highest death-rate from cancer of all European countries, and has maintained this high rate during the present century without showing any marked increase In the meantime the increase in some of the other European countries has been so great that England and Wales, for instance, which in 1881 had only half the crude death-rate from cancer of Switzerland, now equals it The same holds good for Sweden and Holland, while the death-rate for the urban population in Denmark, which by the end of last century equalled that of Switzerland, now exceeds it It is generally

Dr H C Bailey, is entitled Prenatal Care, but also includes many problems of abnormal labour and a discussion of breast-feeding Perhaps its most useful feature is the detailed account which it gives of the ideal régime during pregnancy The medical complications of pregnancy, particularly cardiac disease, are well described, and an excellent chapter on syphilis is included The illustrations, though not original, are well chosen This volume by itself should have a large field of utility, as well as forming an attractive unit of the series Vols II and III, by Prof Clifford Grulee and Dr Barnet Bonar, are devoted to the new-born In Vol II the physiology of the infant is discussed in considerable detail, and anthropometric statistics and the principal factors in growth and development are presented in an unusually readable form An extremely interesting chapter on the circulatory system sets out the characteristics of the infant's blood and also those of heart muscle as shown by electrocardiogram Asphyxia, icterus, and hæmorrhagic disorders are considered in relation to physiology and treatment Vol III. is written from the clinical standpoint, and contains an admirable description of the diseases and malformations met with in the new-born A large amount of recent work has been included and is rendered accessible to the reader by a comprehensive bibliography The authors' presentation of the much-disputed questions of cerebral lesions is one of the best in the literature, the different possibilities in the ætiology are set out extremely fairly, while in general they accept the conclusions of O H Schwartz, and regard the majority of cerebral lesions as traumatic The account of the diagnosis and treatment of these lesions is eminently practical; the difficulties of diagnosis, and the disappointing results of lumbar puncture, diagnostic or therapeutic, are clearly indicated, and a strictly conservative line of treatment is advocated In Vol IV, on Preventive Pediatrics, Prof. Borden Veeder deals with problems of heredity, diet, and management in infancy and childhood in a lucid and convincing manner His methods of infant feeding have the great advantage of being simple and practicable He has little sympathy with complicated formula-feeding, which he considers to have diverted attention from the importance of breast-feeding, as well as being unnecessary and pseudo-scientific Clear instructions are laid down for the composition of simple modifications of milk, and are followed by full diet tables for older children Vol. V, by Dr Bronson Crothers, on Disorders of the Nervous System in Childhood, is the least comprehensive, though by no means the least interesting of the series The author has expressly declined to give an exhaustive account of nervous syndromes, and has limited himself in general to the consideration of two points whether the disease is inevitably progressive or can be arrested, and whether the residual condition can be improved by re-education As a manual of treatment we have nothing but praise for this volume It has the advantage of being written in a spirit of optimism, and of regarding nervous disorder from a dynamic point of view, entirely free from all distinctions of "functional and organic" On the side of diagnosis the book is necessarily incomplete, and in this respect the reader will perhaps experience some of the disappointment which the author foreshadows in his prefatory remarks

These volumes are attractive in appearance, of convenient size, and well illustrated By way of comment and not of criticism, it may be noted that the distribution of space is not very even, while all the volumes fulfil the object for which they were written, some of them go decidedly beyond it The two volumes on the new-born constitute a most exhaustive account of the subject, comprehensive enough for any book of reference, on the other hand, in Vol V., on Diseases of the Nervous System, the author has confined himself largely to matter bearing directly on effective treatment A certain amount of overlapping is inevitable in a series of this kind, cerebral birth-trauma, for instance, is dealt with by different authors in Vols I, III and V, and breast-feeding in Vols I and II The publication of further units in the series will be awaited with interest by readers on both sides of the Atlantic.

Diseases of Infancy and Childhood Ninth edition By L EMMETT HOLT, M D, and JOHN HOWLAND, M D D Appleton and Co 1926 Pp 1018 35s

THE appearance of the ninth edition of this well-known text-book brings with it a reminder of the great losses which American pediatrics has suffered in the last few years Prof Holt, the original author, died in 1924, two years after the publication of the eighth edition Prof Howland, who had undertaken the greater part of the revision of the recent editions, died last June In a preface by Dr E A Park we read that he lived to complete the writing of this volume, though not to see its publication The ninth edition retains very completely the form of its predecessors, there are numerous small additions throughout the text, but on the whole there are few important alterations The account of the treatment of diarrhœa in infants has undergone some modification, the use of protein milk is adopted as the method of choice A fuller description is given of the pathology of nephritis, particularly the acute forms Recent work on tetany and some other nervous disorders has been included A new section has been written on erythrœdema, the author maintains a sceptical attitude towards much of the pathological work which has been published on this subject, and does not accept any nervous lesion as essential The older parts of this book are too well known to require comment The new edition has brought them thoroughly up to date, and will fully maintain the reputation of the work, and perpetuate the memory of two of the most eminent members of the American school of pediatrics.

ROUND THE WORLD WITH A DICTAPHONE By *A Record of Men and Movements in 1926* SIR HENRY LUNN, M A., M D, B Ch London Ernest Benn, Ltd 1927 Pp 301 10s 6d

SIR Henry Lunn's journey was made for the purpose of promoting friendship among the English-speaking peoples and of bringing the Churches into closer union But on this journey he took with him the eyes and the outlook of a man with a sound medical qualification who began life as a missionary, and the book is full of keen observations and amusing stories, many of them told against the author, as when he reached an American town which was placarded in large capitals with "British Peer gives millions for Peace," and when, in commenting on the immense importation of motor-cars into New Zealand, he said he supposed the Maoris did not drive in cars, only to learn that the Maori will sell everything he has to possess a motor-car In various parts of the world he came across old medical acquaintances, as, for example, Prof F Wood-Jones in connexion with ethnological and blood-group studies at Hawaii, and the tragedy of Tasmania, where the last native died 40 years ago without any record having been taken of the folklore or of the habits of an interesting people In New Zealand also he rediscovered an old friend, who proved to be the only commissioned officer in the R A M C who ever rose from the ranks He notes the absence of racial prejudice in New Zealand and the award to a Chinese boy of a Navy League prize, the fact that protective duties result in Australian butter being sold in London at 4d a pound less than its price in the Commonwealth, and the tremendous vogue which the totalisator is having in the same country The volume is well illustrated, and gives a clear picture of impressions gained in many countries by one who disarms the critical reader by his generous enthusiasms The title of the book bears witness to the fact that the chapters were dictated to an instrument while the scenes were still fresh in the author's mind have affected the facilities for hospital treatment Lastly, during the last 12 years or so the American Society for the Control of Cancer has carried out an intensive campaign with the object of educating the public to seek medical advice at the earliest possible stage of cancer The society claims that this campaign has been successful and that a much greater number of patients now present themselves with the disease in an operable stage All these conditions are very different from those obtaining in the limited community of the city of Frankfurt, which formed the material of the investigations of King and Newsholme and of Willcox We are not prepared to assert that these various factors are responsible for the whole of the increase in the death-rate from cancer of the breast and of the female genital organs recorded in the American statistics It is sufficient to realise that this may be the case and that there is no method of evaluating these factors Since the choice between the two alternative explanations is therefore quite arbitrary, the American statistics do not enable us to decide whether the recorded increase is apparent or real An investigation on the cancer death-rate in a limited community with a highly efficient medical service and a stable population is more likely to yield instructive results Such an investigation was actually carried out some years ago by Dr W T Howard[2] for the city of Baltimore Dr Howard found no increase in the mortality from cancer of the breast and cancer of the female genital organs, but actually a reduction Dr Schereschewski, who quotes Dr Howard's investigation, states, however, that in a personal communication Dr Howard informed him that the calculations upon which these conclusions were based are erroneous Dr Schereschewski states further that, on the contrary, the figures furnished by the Bureau of the Census show a distinct increase But the actual figures are not given by Dr Schereschewski, and it is not even stated whether the increase refers to the crude mortality-rate or to the corrected rate It seems highly desirable that the corrected figures for Dr Howard's calculations should be published, for they would furnish a good test for the validity of Dr Schereschewski's assumption on which his conclusions rest If it be true that throughout the whole ten registration States the diagnosis and death certification for cancer of the accessible sites has remained uniformly accurate during the period 1900–20, then the increase in the mortality from cancer of the breast and female genital organs in Baltimore should be of the same high order as that recorded for the ten registration States If the figures are found to be distinctly lower for Baltimore, Dr Schereschewski's assumption would be shown to be unfounded and the problem would require further analysis

Our point is not to deny a real increase in the death-rate from cancer, but rather to plead for a recognition of the strength of the arguments against this view If the statistics of large communities give prima facie evidence of a real increase in cancer, as is the case not only for the United States but also for England and Wales, as shown in the Registrar-General's Report for 1917, why is this increase not revealed by statistics of small communities such as Frankfurt, Baltimore, and Switzerland, in which the conditions for accurate registration are highly efficient and which should give, therefore the most accurate reflection of this increase? Until this discrepancy is accounted for satisfactorily the contention that the increase in cancer is real remains unproven

FAT AND TUBERCLE

Long ago Hughes Bennett suggested that the main causes of tuberculosis were the dearness of butter and the abundance of pastry-cooks, the poor, he said, do not get sufficient fat, and the upper classes disorder their digestion by puff-paste The part played by fats in the household of the body, although not as yet fully determined, is unquestionably very large and the shortage of fat during and after the war brought this home to many who had previously been sceptical on the point Shortly before the armistice Prof E H Starling was requested by the Scientific Food Commission to set out the evidence, as it then existed, for the indispensability of fat He was unable to find good evidence for a strict lower limit of necessity provided that the caloric value of the diet as a whole was sufficient to meet the needs of the body but he pointed out that the breast-fed infant's diet owes 50 per cent of its total energy value to fat, and that up to the age of 6 years a percentage of 35, and thereafter of 20–25, should be regarded as the minimum desirable. These proportions can be augmented without interfering with efficiency or with health, and, Prof. Starling thought, diminished without serious detriment to health, though probably not without inconvenience and diminution of efficiency He had not before him then the evidence which we now have of the great increase of tuberculosis in countries where the fat ration was most restricted And at that time not much attention had been paid to the distribution of the accessory factors in animal and vegetable fat, although Prof J C Drummond had expressed a desire to enforce the addition to margarine of a proportion of cow butter, egg yolk, or oleo-oil to provide an adequate source of the fat-soluble factor. Evidence which has since accumulated in Central Europe points to the importance of this element of the diet in raising the resistance to infection from tuberculosis More than that, part of the accepted treatment of a case of pulmonary tuberculosis is "feeding up," in which process fat undoubtedly plays an important part, and where there is risk of infection the common sense prophylactic measures include a satisfactory diet, rich in fat As a contribution to this subject, a small but intensive study by Dr W B Vaile, appearing on p 72 of our present issue, will certainly be read with interest Dr Vaile investigated in all 24 families consisting of 162 persons, he went carefully into all the possible factors and was struck with the varying tendencies exhibited by different members of the families towards fat It was possible, he found, to separate two distinct groups of "fat-eaters" and "fat-shy" individuals, and when these groups were investigated with regard to pulmonary tuberculosis the results were remarkable. Of the 101 fat-eaters, 96 were alive and well, 4 certainly had pulmonary tuberculosis, and 1 doubtfully so. There were 61 "fat-shy" persons, of whom only 11 were alive and well, 48 certainly had tuberculosis, all pulmonary except 2, in which the localisation was hip and ankle respectively, and the remaining 2 had doubtful tuberculosis To complete the story, there were also 2 persons alive and well about whose food habits no information could be obtained

The examples given in Dr Vaile's paper illustrate these results, although they give little indication of their correct explanation The statistical investigation of pulmonary tuberculosis is notoriously fraught with difficulties Even the well-known and much-quoted results obtained by Karl Pearson as to the inheritance of a tuberculous diathesis have been criticised in the light of evidence agreed—except by uncritical or uninformed writers—that a large proportion of this increase is apparent and not real This is due to a variety of factors inherent in the pathology of cancer Cancer is a disease of middle age and of old age, and since more persons now reach the cancer age owing to more successful treatment of other diseases and the absence of epidemics, this in itself is bound to increase the "crude mortality-rate" from cancer This fallacy can be corrected by appropriate calculations Another disturbing factor is the difficulty of diagnosing cancer, owing to the absence of specific symptoms A large number of cases of cancer are therefore not diagnosed as such during life, and in the absence of a post-mortem examination are recorded under another cause of death than cancer The number of such cases gradually diminishes as our knowledge of the disease increases and as new methods of clinical examination, such as the cystoscope, the sigmoidoscope, and X rays are being introduced and becoming more universal in their application But an examination of hospital post-mortem records has shown that even under the most favourable conditions the number of cases of cancer which die without the disease being recognised amounts to no less than about 25 per cent Another factor which has not received sufficient consideration is the greater frequency with which cancer is now being diagnosed in its earlier stages and the resultant greater frequency of operative treatment When the disease is diagnosed in its earlier stages the patient and the patient s relatives are necessarily acquainted with the nature of the disease in order to justify the necessity for an operation After the operation the diagnosis is confirmed by microscopic examination The diagnosis of malignancy is thus "fixed" for this particular case, and if the patient dies within five years after the operation the case will be returned as cancer whether a post-mortem examination is made or not But if the diagnosis is made late when the case is inoperable, the nature of the disease may be kept from the patient and even from the patient s relatives, and as the diagnosis has not the same certainty the medical man in attendance may prefer to return the case as other than cancer It is surely more than a coincidence that there is one country in which the medical man in attendance gives two certificates of death, one to the family as a prerequisite to burial and another one as a confidential report of the cause of death to the Statistical Bureau, and that in this country—Switzerland—the recorded mortality from cancer has always been high and has shown no increase for the last 25 years

[2] Jour Amer Med Assoc, 1923, lxxx

It was a great advance in our understanding of the significance of cancer statistics when G KING and A NEWSHOLME in 1893 pointed out that errors in diagnosis must necessarily affect more the death rate from cancer of inaccessible sites, such as stomach and intestine, than of accessible sites, such as the breast and female genital organs They analysed accordingly the death-rate from cancer of these two groups in a restricted community with a highly efficient medical service—the city of Frankfurt—where records for the death rate from cancer of different sites were available They found that the increases in the cancer mortality during the period of 1860–87 fell entirely on the inaccessible sites, and a continuation of their studies by W E WILLCOX showed exactly the same relationship for the succeeding period up to 1913 The mortality returns for cancer of the accessible sites showed therefore during the whole of the period the same degree of reliability, and the fact that the increase in the total cancer death-rate fell entirely on the inaccessible sites was accepted as evidence that this increase was an apparent one due to improved diagnosis, and not a real one That is a reasonable argument But it is an obvious logical fallacy to invert this sequence by arguing that an increase in the death-rate from cancer of the accessible sites necessarily represents a real increase Such an increase might also quite well be due to such factors as more accurate diagnosis or more frequent operative treatment This is the fallacy underlying the argument in a recent official publication issued by the United States Public Health Service and entitled "The Course of Cancer Mortality in the Ten Original Registration States for the Twenty one-year Period, 1900–1920"[1] This Bulletin contains in an appendix 114 tables giving the death rates from cancer in the ten registration States arranged for the different age groups and according to the different sites In the text, which has been written by Dr G W SCHERESCHEWSKI, this statistical material is very clearly analysed and corrections are made for those various errors which can be evaluated statistically After having made all those deductions the figures show a considerable increase in the total death rate from cancer during the period 1900–20, and this increase is due not only to cancer of inaccessible sites, but also to an increase in cancer of the accessible sites At this point Dr SCHERESCHEWSKI makes a bold assumption He holds that the accuracy of diagnosis has remained the same for the whole of the period On this point he writes (p 51) "While there is still much room for improvement in diagnostic skill leading to early diagnosis of the disease, when cancer of even inaccessible sites has progressed to a stage where death is imminent, in a great majority of instances the symptoms at that time are so characteristic and pronounced that no difficulty should be experienced, even by the medical tyro, in determining the cause of death From the standpoint of professional skill permitting the recognition of cancer in the agonal stages, it does not seem probable that the physicians of 1900 were much, if at all, inferior to their brethren of to-day" On a previous page (p 47) he speaks of "cancers of accessible sites as the buccal cavity, breast, female genital organs, and the skin in which errors, *so far as death certification is concerned* (the italics are ours), hardly ever occur"

Starting from these premises Dr SCHERESCHEWSKI is enabled to conclude from the statistics that the increase in the death-rate from cancer of the accessible sites is real and not apparent, and that the contrary view is no longer tenable But the assumption of the accuracy of death certification and of diagnosis which he makes is not supported by any evidence, statistical or otherwise It is merely an assertion, and if anyone chooses to disagree with it the whole conclusion falls to the ground It would, in fact, be easy to make out a good case against Dr SCHERESCHEWSKI S assertion The statistics refer to a vast district, as extensive as the whole of Western Europe, in which an enormously rapid development has taken place during the period of observation The population has increased from 20 millions to 27 millions, means of communication have greatly improved, there has been an enormous advance in medical education all over the United States and especially in the ten registration States, so that to day many look to the States as a model of progressive medicine This change must necessarily weeks. This restores the blood-sugar to normal, gives the patient an adequate carbohydrate diet and repairs his nutrition as far as possible. Dr. Nixon is vehement in his condemnation of under-nutrition in the treatment of diabetes and quotes Mosenthal's dictum that, whereas insulin diminishes the blood-sugar and sets aside glycosuria by allowing the body to utilise more glucose, starvation allows the accumulated glucose to escape in the urine. Starvation is floating a stranded ship by jettisoning her cargo while insulin treatment takes her off on a rising tide. Insulin allows of the storage of glycogen that is so important after operation; under-nutrition depletes the store. Apart from these risks there is a peculiar danger for diabetics in anæsthesia. All anæsthetics produce a rise in blood-sugar, chloroform being the worst: local infiltration may cause extensive necrosis and spinal anæsthesia may produce coma. Pre-operative starvation by itself may result in post-operative acetonæmia and acidosis, even in a non-diabetic, and for the diabetic no form of anæsthesia is safe until he has assimilated an adequate amount of carbohydrate. It is sugar that protects him from infection, shock, and coma, and insulin raises the blockade and allows the blood-sugar to come to the relief of the beleaguered tissues. Post-operative shock always brings an interference with the internal respiration, to which the effect of a general anæsthetic may be chiefly ascribed, and which causes, according to Dr. D. Fisher,[2] internal acidosis and asphyxia, with lessened oxidation within the cell. By improving the oxidation it is possible to hasten recovery from shock, and Dr. Fisher has devised a form of treatment on these lines. The diabetic patient has these oxidative processes already impaired when he comes to operation, and is therefore predisposed to post-operative shock. The first reaction of the organism to shock is to mobilise all the available glycogen in the blood stream and distribute it to the cells, but since this supply is soon exhausted it is most important that it should be quickly replenished. Insulin, which enables glucose to be administered in an oxidisable form, is rational treatment for shock in diabetics and non-diabetics alike.

EARLY LEPROSY IN THE CHILDREN OF LEPERS.

THOUGH leprosy has been known throughout the ages, it remains one of the most puzzling diseases and there is still uncertainty about some of its most important features. The literature, for example, is still cumbered with innumerable estimates of the incubation period ranging from a few months to 30 years, whilst the initial lesion, method of invasion, and portal of entry are all still in doubt. This unsatisfactory state of affairs is due to the long incubation period and slow development of the disease, to the failure of attempts to transmit the infection to lower animals, and to the difficulty of gathering observations of the early symptoms in a number of cases large enough to permit of definite conclusions being drawn. Dr. José N. Rodriguez[3] has taken the opportunity to study the early manifestations of the disease in children, some of whom became lepers, and all of whom had lived with leprous parents—most of them continuously since birth. Of 398 children of leprous parents, 59 (14.8 per cent.) were bacteriologically positive; 11 (2.8 per cent.) were clinically lepers but bacteriologically negative; 97 (24.4 per cent.) had suspicious signs; 231 (58 per cent.) were non-leprous. The sexes were almost evenly represented. The incidence of leprosy was practically identical in both sexes up to the eighth year, but from 8 to 12 there were twice as many males as females. The influence of puberty, naturally more pronounced in girls, is perhaps manifested in the fact that from 12 to 16 years of age the incidence among females rose to exceed the figure for males by 10 per cent. Incidence increased with age—i.e., with longer exposure to leprous parents. The youngest leper bacteriologically positive was a girl 18 months old, in whom the first lesion (macular) had been noted at the age of 8 months. Half the confirmed lepers became bacteriologically positive between the ages of 3 and 6 years, the average age being 5 years and 9 months. In view of the frequent finding of lepra bacilli in the blood of lepers the possibility of transmission during pregnancy from the maternal to the fœtal circulation was investigated. Sugai and Monobe (1913) found lepra bacilli in four of 12 placentas of leper mothers and lepra cells in 6 others, and also demonstrated the bacilli in 10 of 12 newly born babies and in blood of a 17 months old child of a leper mother. D. San Juan (1919) found acid-fast bacilli in globi form in placentas of lepers. In the examination of 15 placentas Dr. Rodriguez found four in which there were lepra bacilli in the cord at the fœtal end, twice in globi form. In only one of these were bacilli found also in the placental tissue. It is evident, therefore, that the bacilli reach the fœtus through the placental circulation in a considerable proportion of cases. This is apt to occur when the pregnant mother develops the so-called lepra fever, with its accompanying bacteræmia. Thus of 19 children of mothers having lepra fever during pregnancy, 3 became lepers; while only 5 children became lepers out of 100 whose mothers did not have lepra fever in pregnancy. Congenital manifestations of leprosy are unquestionably rare; no case was found in the 871 children born at Culion up to 1924, the earliest suspicious lesion being seen at the age of 3 months. Hereditary transmission of a predisposition to leprosy is difficult to prove, and if it exists plays only a minor rôle in the spread of the disease. In the parents at Culion leprosy did not give rise per se to an increased incidence of congenital debility in the offspring.

Treatment with chaulmoogra oil derivatives was given to 184 leprous mothers before and during pregnancy, whilst 58 had no treatment; but in both groups half the offspring became lepers. Breast-feeding was not an important factor in the transmission of leprosy from mother to child. Sugai and Monobe (1916) had discovered lepra bacilli in the milk of leper mothers in two cases, but in not one of 45 cases examined at Culion could they be found. Most of the women with infiltrated nipples were sterile, and indeed, involvement of nipples was more often noted in males than in females. In fact, leprosy at Culion was twice as common in bottle-fed as in breast-fed children; as a rule the latter were in better condition, which shows that the better the health of the child the less its chance of acquiring leprosy when exposed to infection. Although in some cases the itch of scabies undoubtedly served as the portal of entry in leper children, scabies and other skin diseases did not in general predispose to infection with leprosy, and the higher incidence of leprosy was actually found among children who had had no skin disease. Since the leper parents, especially the mothers, are in more intimate contact with their children than is any other person, they are chiefly responsible for infecting their own offspring. Fewer children become infected when the type of leprosy in the parents is neural than when it is the more contagious cutaneous or mixed type. Many authorities contend that there is no initial primary lesion—that the invading lepra bacilli produce no appreciable lesion at the point of entrance: they believe that, once having gained a foothold in the body, the bacilli may remain latent for varying lengths of time, after which if conditions become propitious, they may multiply to produce manifest leprosy. In favour of this view is the observation of Sorel and Leboeuf that acid-fast bacilli may exist in the lymph glands of apparently normal individuals who have lived with lepers. In the Culion children, however, Dr. Rodriguez found in 75 per cent. of those who became definitely lepers a single initial lesion in the skin and he marshals data in support obtained, particularly in France, by the removal of children from a source of infection early in life, who then grow up with actually less "tendency" to tuberculosis than the population at large The explanation of this, and possibly other difficulties, lies in an appreciation of the fact, insisted upon again largely by the modern French school, that it is infection in the very earliest months of life which counts, and that pulmonary tuberculosis in later life represents a reactivation of an old process or a superimposed reinfection If this is so, it may be that the relationship between fat in the diet and pulmonary tuberculosis is to be explained by supposing that the absence of desire for fat is one of the general symptoms of latent tuberculous infection The child with the "habitus phthisicus," who is probably already infected, may dislike fat just as the child who suffers from cyclical vomiting often shows a marked liking for fat, or as the pregnant woman affects curious articles of diet, the like or dislike being possibly associated with biochemical conditions On the other hand, it may really be, as Dr VAILE suggests that the people who eat fat escape the development of infection because their resistance is higher than that of the "fat-shy" group How resistance is raised by the intake of fat is, again, a matter for speculation The good results of cod liver oil in pulmonary tuberculosis may throw some light on this, for the antirachitic vitamin is apparently concerned with the process of calcification, and the ultimate cure of pulmonary tuberculosis is generally associated with the laying down of lime salts in the healing lesion Incidentally, it would be interesting to learn if the dislike for cod-liver oil, present in certain people, is more frequent in those with tuberculosis, as would seem likely from Dr VAILE's results He submits some evidence that fat taken under compulsion is as effective in preventing tuberculosis as fat taken with avidity although many physicians agree with LAUDER BRUNTON that the instinct of some children who refuse to eat fat is perfectly right Fat is undoubtedly a costly item in the daily dietary, but it will be an added reason for encouraging its use if Dr VAILE's results can be confirmed on a large scale

TUBERCULOSIS SOCIETY —A meeting of this society will be held on Friday, Jan 11th, at 1, Wimpole-street, London, W, at 8 P M, when Dr C D Agassiz will read a paper on the Differential Diagnosis of Non-Tuberculous Fibrosis of the Lungs A discussion will follow

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Jan 27th the lectures on Emergencies in Medicine and Surgery will be continued at 5 P M, at the rooms of the Medical Society of London, Dr L S Burrell will lecture on Hæmoptysis, the lecture being free to members of the medical profession The clinical demonstrations in surgery and ophthalmology will also be resumed during the month Courses in January, which have already been announced, are Jan 10th to 22nd, Medicine, Surgery, and the Specialties, at the Prince of Wales's General Hospital, Jan 10th to 22nd, Diseases of Children, at the Children's Clinic and the Royal Free Hospital, Jan 11th to Feb 5th, by-weekly lecture-demonstrations, at the Bethlem Royal Hospital, and Jan 17th to 29th, Cardiology, at the National Hospital for Diseases of the Heart From Jan 31st to Feb 26th the London Lock Hospital will hold a comprehensive course in Venereal Diseases A special course in dermatology will be given at St John's Hospital from Jan 31st for four weeks Classes in pathology can also be arranged From Feb 7th to 19th there will be an all-day course in Diseases of Children held at the Paddington Green and the Victoria Hospitals For one week, starting on Feb 21st, a general practitioners' course will be given at the Royal Northern Hospital, no fee will be charged Syllabuses of the special courses and copies of the general course programme and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship, at 1, Wimpole street, London, W 1

Annotations.

"Ne quid nimis"

NEW YEAR HONOURS

THE list of Honours published on Jan 1st, which was a small one, recognises the work of medical men in various parts of the Empire Neurologists everywhere will rejoice at the knighthood conferred on Dr Henry Head, F R S, whose work has cleared up dark places in the structure and function of the nervous system for his own and future generations Dr Thomas Houston, who also receives a knighthood, has filled many positions in Queen's University, Belfast, and made his influence felt in public affairs Colonel Corrie Hudson, C I E, D S O, who has been awarded the C.B, Military Division, is Assistant Director of Medical Services at Aden, and Lieut-Colonel John Wolfran Cornwall, I M S retd, who has been made C I E., directed until recently the Southern India Pasteur Institute In offering hearty congratulation on behalf of the medical profession to colleagues who have received well-deserved honours, we extend our good wishes to the Rev Edwin William Edward Lant superintendent of the Leper Home and Hospital at Dichpalli, Hyderabad, and to Miss Rose Harvey, superintendent of the Nasik Leper Asylum, Bombay, who have received the Kaisar-i-Hind medal of the first class, as well as to two other women whose appointment as C B E follows on distinguished work in preventive medicine—Mrs Grace Thyrza Kimmins, founder of the Heritage Craft School for Crippled Children, and Miss Katherine Jane Stephenson, vice-chairman of the Wilts Public Health Committee

INSULIN IN SURGERY

THE diabetic patient has always been a severe trial to the surgeon High sugar-content in the blood renders a person very susceptible to local infection, and diabetics require surgical treatment of boils, dental abscesses, pyelitis, appendicitis, and pelvic and other suppurations more often than do non-diabetics But, in the words of Sir Frederick Treves, "Diabetes offers a serious bar to any kind of operation A wound in a diabetic patient will probably not heal, while the tissues appear to offer the most favourable soil for the development of putrefactive and pyogenic bacteria" The preparation of insulin has, therefore, been as great a blessing to the surgeon as it has to the physician, and Prof J A Nixon has recently described its surgical employment in a paper read before the Bath and Bristol Branch of the British Medical Association[1] Dr Nixon does not agree that once a patient starts taking insulin he must continue throughout life Many patients of local infections are undiscovered diabetics or potential diabetics Their carbohydrate tolerance is low but sufficient to deal with an adequate diet When they contract an infection their tolerance is lowered, with the result that they can no longer metabolise sufficient carbohydrate, and their resistance to infection is dangerously decreased The surgeon should not hesitate to use insulin here When the patient has successfully overcome the infection, his carbohydrate tolerance may rise again and the insulin can be discontinued To impose a strict dietary is highly dangerous, for the diabetic with an infection needs more carbohydrate, not less The only way to enable him to utilise it is to give insulin in proportion to his carbohydrate demand In true diabetic gangrene insulin treatment should never be delayed, even if it does not cure the gangrene, it will add considerably to the chances of success in operation, which without it will probably fail A deliberate operation, for whatever cause and of whatever magnitude, should always, in Dr Nixon's opinion, be preceded by a course of insulin lasting two or three palatability on which the bulk of money is thrown away A number of prescribers are not content to add a simple syrup to a mixture but require this syrup to be flavoured with virginian prune or tolu and frequently to be conveyed in a vehicle of chloroform water The addition of chloroform water to a prescription containing syrup of squills adds 1½*d* to its cost, and to make up a mixture containing compound tincture of cardamoms with peppermint water costs 5*d* more than plain water In a few instances the flavouring agent of a prescription has cost more than the active drug, as in a mixture containing 3 drachms of iron and ammonium citrate made up with orange water, where the salt cost 1½*d* and the solvent 6*d* Various devices have been adopted in the local formularies, framed by certain panel committees or groups of committees, to get over the excessive price of such vehicles as chloroform and peppermint water In these all B P aquæ are prohibited and concentrated solutions used instead, chloroform is dispensed in the form of an emulsion The tariff for all these drugs is based on B P or B P C standards and is, of course, part of the contract made with the pharmacists under the Insurance Acts Separation of the prescribing and dispensing for insured persons was no doubt a wise move, but it was at the same time costly, and it is significant that the cost of drugs prescribed is actually less than the dispensing charge in many insurance areas The Dundee Panel Committee calls the attention of practitioners to the fact that the great demands on the Drug Fund make it imperative to take every care to avoid unnecessary and wasteful expenditure The abolition of the placebo would be a great step in this direction, but one which would require the assent of the insured population, and the bottle-of-medicine habit dies hard In one respect the year 1926 has shown a welcome standardisation in Dundee where the practice of prescribing a 6-ounce mixture in dessert-spoon doses has become practically universal The report contains much food for thought

THE SUPRARENAL AND THYROID GLANDS IN PELLAGRA

Dr H M Shelley's observations on pellagra in Nyasaland, which we publish on p 74, point to changes in the thyroid gland, with deficiency of thyroid secretion, as the essential lesion in the disease As a control, it is of interest to note the results of an experimental investigation of pellagra by Dr L Karczag In a first series of experiments his maize-fed guinea-pigs developed loss of hair, gastro-intestinal catarrh, and paralysis, partial or complete, of hind legs These symptoms, however, were found also in guinea-pigs infected with tubercle He had concluded that there was no identity between the acute maize disease of guinea-pigs and the chronic human disease, pellagra In later researches,[1] however, undertaken with Dr Irene Barát in Budapest, he has been able to demonstrate in maize-fed guinea-pigs, besides a characteristic herpes of lips and nose, definite capillary and parenchymatous changes in the suprarenal glands and red blood-cell destruction and deposition of free iron pigment in suprarenals, liver, and spleen These lesions occurred equally whether the maize-fed guinea-pigs were white or piebald, or were kept in daylight or in the dark He notes that in human pellagra Kozowsky had found deposition of free iron pigment in suprarenals, liver, heart muscle, central nervous system, and peripheral nerves, and declared these changes to be especially characteristic of pellagra There is also a rather close resemblance in many features between pellagra and Addison's disease Karczag concludes that essentially pellagra is a lesion of the chromaffin system, involving the sympathetic nervous system and the endocrine glands It will be seen that this is not inconsistent with, but rather in support of Shelley's contention There remains the all-important question of ætiology Karczag's animals were maize-fed, but Shelley's observations exculpate maize as a factor in the production of pellagra in Nyasaland

THE CURE OF WHOOPING-COUGH

INNUMERABLE claims have been made for the cure of whooping-cough, but the methods suggested have always proved to have at best only a limited value Recent articles from different sources recommend two kinds of treatment which are of interest because neither requires the use of drugs and both are based ultimately on the hypothesis that imperfect oxygenation is the cause of the attacks and the disease will end within 21 days if this deficiency is remedied Dr E Pietranera[1] working on lines suggested by Fretin,[2] of Paris, advocates periodical movements of the chest, they may be active or passive according to the age of the patient The movements are designed to stimulate deep breathing and are repeated every two or three hours In infants they consist of alternate light compression and relaxation of the lower ribs, as in artificial respiration, whilst older children are taught breathing exercises Nageli's method, which consists of applying pressure to the base of the tongue from outside, may be used to cut short the spasmodic attacks, or else the method of Josè Panna, who advocates deep pressure on the epigastrium, rapidly applied and kept up till the attack ceases Dr G Boeldieu[3] claims good results in the treatment of whooping-cough by the means originally described by H Chatiniere in 1921 Subcutaneous injections of nascent oxygen are given every two days, the quantity being at first 50 c cm and later, if necessary, 100 c cm Of 18 cases so treated he reports that in 16 the attack ended in 15 days, whilst the other two were cured within three weeks These results are very similar to those which Dr Pietranera got by making the children breathe deeply He, too, treated only 18 cases, but all of them successfully Like other writers, he lays special stress on the value of open air and recommends treatment at home where possible, because there is a strong nervous element in the disease and children may involuntarily imitate the attacks of others Of the two methods his is certainly to be preferred as it is simple, needs no apparatus, does not cause pain—an important point with small children—and can be carried out by the older children themselves, in any case deep breathing is probably beneficial to the organism Treatment by injection of oxygen might, however, be tried in bad cases where the means are at hand and where manipulative treatment is undesirable.

INDUSTRIAL ALCOHOL AS A BEVERAGE

DEATH is a drastic punishment for secret drinking Reports from the New York correspondents of the daily newspapers gravely state that in 1926 about 2000 people died in the United States as a result of drinking so-called whisky prepared from denatured alcohol Public opinion is now aroused in that country, and apparently there is some likelihood of the industrial alcohol sold there being rendered for the future merely nasty and not deadly Denatured alcohol, or methylated spirit as it is usually called here, was introduced in 1853 in response to a widespread demand for cheap alcohol for industrial purposes, the great cost of alcohol being then, as now, due rather to taxation than the expense of production It consists of ethyl alcohol rendered unfit for drinking by the admixture of about 10 per cent of wood naphtha or crude methyl alcohol Towards the end of the late war a violet colouring matter was also added and " ordinary " methylated spirit, as distinguished from the better kind known as " industrial," contains enough mineral naphtha, or light paraffin oil, to make it cloudy when mixed with water Methylated spirit as thus composed is of his belief that this was the primary initial lesion. In the other 25 per cent the first clinical manifestations were multiple macules appearing simultaneously or a generalised rash The commonest sites of the initial lesion were the buttocks, the cheeks, the posterior and lateral surfaces of the thighs, and the loins The primary lesion was never seen on chest or abdomen, although these regions often showed lesions in the more advanced stages of leprosy The initial lesion was a solitary pale or pinkish macule, and in three cases this primary macule started from a scabies scar

Rogers and Muir calculated incubation period by supposing susceptibility to be equal throughout the whole time of exposure, taking half of this period as the average time of infection, they added the time which had elapsed between isolation and the appearance of the first sign of the disease Using this method, Dr Rodriguez calculates that the probable average incubation period among the segregated and unsegregated Culion children is three years and nine months The period of observation of children of lepers segregated after 6 months of age should cover at least five years, for one child developed the first suspicious signs four years and two months after isolation Segregation of the children of lepers delayed *after* the age of 6 months did not decrease the incidence of leprosy, nor did it delay the appearance of the disease The removal of children of lepers from a leprous milieu immediately after birth is the only safe prophylactic measure The experience of the Almona Settlement in India during 30 years, and of the Molokai Settlement in Hawaii during 15 years, has made it certain that such a measure is effective In both these leper settlements but one child so removed has become a leper Dr Rodriguez and the Philippine Health Service are to be congratulated on a valuable contribution to our knowledge of leprosy

RESEARCH IN ANIMAL BREEDING

THE Animal Breeding Research Department of the University of Edinburgh has gained an international reputation, and the sixth annual report of its director makes interesting reading, both because it deals with varied investigations and because it describes extraordinarily rapid progress Although projected as long ago as 1913, the department did not get seriously to work until 1921 Even then it was in very humble circumstances, but it was under the directorship of Dr F. A E Crew, and within these few years the importance of its labours has so impressed the scientific world that the Rockefeller International Education Board offered £30,000 for its development on condition that an equal sum was raised from other sources [1] The present report contains, by way of postscript, the intimation of a gift of £10,000 from Lord Woolavington The sphere of work is likely to be enlarged and its educational value increased, and already a number of foreign research workers have been attracted to the school Much of what is done has an almost immediate application to practical agriculture, but the temptation to be merely utilitarian has been eschewed To quote the director "The suggestion that if such and such problems were solved vast sums of money would be saved may be of profound economic interest to the economist and the statesman ; it will certainly interest the scientist as a citizen, but it does not constitute the kind of stimulus that provokes him to ardent investigation" Such problems, however, as fertility and fecundity in sheep and studies in the fleece qualities of various breeds and crosses have a great academic interest as well as an obvious economic application The same holds good of a series of studies in sterility in the horse—studies which suggest that the mode of inheritance of a certain form of sterility is comparatively straightforward In pigs these problems are being investigated from a different aspect—namely, the breeding of a more prolific stock During the course of the year several papers have been published on endocrinology, with special reference to the sexual glands, and Dr Crew has two interesting contributions on the subject of rejuvenation He has shown that in the fowl unilateral vasoligation does not cause rejuvenation in the senile male—a result which gives no support to the claims of those who recommend the operation for the restoration of mammalian youth On the other hand, he finds that the feeding of desiccated thyroid to aged fowls of both sexes has definite rejuvenating effects, such as the resumption of egg laying by the females These are only examples of the interesting information contained in the director's statement, and we note that reprints of published papers will be sent to any person interested The unassuming format of the present report is becoming to an institute which is urgently in need of funds

PYORRHŒA ALVEOLARIS

THE treatment of pyorrhœa alveolaris, with which Mr G B Pritchard deals under another heading in our present issue, must wait on diagnosis, a truism which only needs emphasis because it is so liable to be overlooked in this condition The diagnosis of pyorrhœa depends on the recognition of periodontal pockets around the necks of the teeth produced by a process of ulceration occurring in the periodontal membrane The differential diagnosis lies between it and gingivitis, and all gradations are found between a simple superficial gingivitis and an advanced pyorrhœa existing either separately or together and running either an acute or chronic course The symptoms are often identical—i e , hæmorrhage from the gums—either spontaneously or after brushing They both may produce a purulent discharge from the gum margin, and both are most important causes of oral sepsis Clinically the manifestations of a gingivitis are superficial, of pyorrhœa deep as well as superficial. An acute gingivitis may produce considerable sloughing of the gingival margin and superficial parts of the adjoining gum, but the alveolar gum cannot be separated to any extent from the necks of the teeth A chronic gingivitis may produce considerable hypertrophy of the gum margin which may ulcerate freely, but the pockets associated with it do not descend below the necks of the teeth An acute pyorrhœa alveolaris may produce paradental abscesses, but although deep-seated they are lateral to the roots and not apical A chronic pyorrhœa of any length of standing destroys the normal festoon of gum at the necks of the teeth, and produces varying amounts of gum recession, and further still the membrane deep to the receded gum margin is destroyed leaving the pockets between the root and the alveolus, which are diagnostic whether or not there is visible pus Radiographically, the marginal absorptions of alveolus is little or absent in gingivitis while in pyorrhœa a varying amount of absorption is always visible with destruction of the superficial compact bone

THE COST OF DRUGS IN PANEL PRACTICE

THERE seem to be careless prescribers in Scotland as well as in other parts of Great Britain The epithet is that of the Dundee Panel Committee which returns in its report for 1926 to the expense to the Drug Fund involved in careless prescribing It might be more accurate as well as more courteous to use the term elaborate prescribers to indicate those who regard the taste and colour of a mixture as of equal importance with its active ingredients Leaving out of account modern organic preparations with a few exceptions, such as potassium iodide, the commoner pharmacopœial drugs which are well proved in private and hospital practice are inexpensive while it is the newer forms of medication whose value may be in doubt which are costly A consideration of prices, the report remarks, would almost lead one to conclude that the cost of a drug is inversely proportional to its therapeutic value But it is mere within limits there is no objective optimum and that only extremely violent changes in the stimulus can produce any significant variation in the reaction—are found in other psycho-physiological fields For example, it is no longer believed that there is one objectively best way of performing a manual operation in a given industrial process " Anyone who studies his report will agree with Mr Pyke that the problem is complex and elusive, and many questions have been raised which have not been answered The practical typographical problems of legibility are still far from scientific solution, and such solution will not be possible until many problems of principle, method, and technique have themselves been solved Further investigation is now to proceed as a part of a broader study of the physiology of vision and will have the goodwill of all save the cynic who thinks that what is really needed in this world is some means of making print illegible

FORMS OF MALARIAL PARASITE

THOUGH many morphological variations of the malaria germs are recognised it is now generally admitted that only three definite species exist as parasites of man throughout the world Neither the views of Laveran on the unity of the genus plasmodium nor the plurality of the subtertian parasite, *Plasmodium falciparum*, as advanced by Grassi and Feletti, have gained general acceptance The publication in 1914 by J W W Stephens of a new species of malaria parasite under the name of *Plasmodium tenue* occasioned considerable comment amongst malariologists The main claims to distinction on the part of this new parasite were the marked amœboid forms, the large size of the nuclear chromatin, and the irregularity in shape of the schizonts A Balfour and C M Wenyon pointed out at the time that such distorted forms were not uncommon in *falciparum* infections, and on these grounds were unable to recognise *tenue* as a distinct species Now, in the October issue of that progressive periodical the *Kenya Medical Journal*, J C J Callanan has been able to show, by means of three excellent plates of camera lucida drawings, that *tenue* forms of the parasite can be demonstrated in the same preparations as ordinary " ring-forms " of the subtertian parasite, and that the former are found only in distorted red blood corpuscles which have been subjected to pressure, none being demonstrable in those portions of the blood slide where the cells are superimposed That *tenue* forms are indeed artefacts is conclusively proved by their absence from fresh preparations of subtertian malaria blood In *tenue* cases which came to autopsy preparations from the brain and spleen invariably showed parasites identical with *falciparum* In blood films in which too great pressure has been exerted in their preparation the majority of the *tenue* forms lie in one general direction, at right angles to the edge of the film The question of the existence of a fourth form of malarial parasite seems thus to have been definitely settled

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCV —THE TREATMENT OF PYORRHŒA ALVEOLARIS

THE methods employed in the treatment of pyorrhœa are so various and differ so much in accordance with the local and general conditions associated with it, that it is difficult to indicate any one that is definite and sharply defined

Advanced Cases

In the advanced case with a large amount of destruction of the supporting tissues of the teeth, with marked oral sepsis definitely established, and possibly with manifestations of focal infection in other parts of the body, it is impossible to produce any but a slight improvement of the local condition by conservative treatment Radical extraction of the teeth is the only method which offers any hope of a cure, and even then a low grade infection of the alveolus may persist for years and give rise to a progressive absorption of what bone is left Locally the jaws remain tender and artificial dentures are badly tolerated Radiographs show a " feathered " appearance at the margins of the jaws and from these " feathered " patches micro-organisms can be cultivated Curetting followed by vaccine treatment seems to offer the best method of control

Early Cases

In the early case where the peridental infection is confined to the gingival margin, or has spread only to the superficial fibres of the periodontal membrane, conservative treatment offers very fair prospects of success In the great majority of cases pyorrhœa starts as a localised gingivitis and some time usually elapses before it can spread any distance Injury, the result either of food stagnation or of mechanical trauma, closely followed by infection, is the main cause of these localised patches, and they are often seen round the lower third molars as they are erupting, especially when the eruption is delayed by impaction or limitation of space In such cases pressure can be transmitted as far forwards as the canine teeth, resulting in a mechanical congestion of all the gingival margins and so predisposing them to the infection which follows Crowding and misplacement of other teeth have a similar effect Mechanical congestion of the gums associated with food impaction is always followed by a gingivitis Seruminal calculus is then deposited, and acts as an additional irritant, thus a vicious circle is set up and pyorrhœa becomes established Treatment lies in the removal of the cause of the congestion and the making of the mouth and teeth self-cleansing

Sometimes the relief of pressure by extraction of the third molars is sufficient, in any case this procedure makes the cleaning of the back of the mouth a comparatively simple matter For relief of congestion elsewhere, orthodontic treatment, either mechanical or preferably, and if possible, extractive, is employed; as the position of the teeth in the arches improves natural cleansing also improves, stagnation of débris disappears, and, congestion being relieved, the deposition of seruminal calculus is checked To complete the treatment and generally before the extraction, or during the orthodontic treatment, the calculus and all débris is removed by scaling and polishing An astringent application such as glycerine and tannin is used for a few days, together with a mouth-wash containing chlorate of potash In most cases no further treatment is required except a periodical scaling ; in all the patient must be taught the necessity of thorough artificial cleaning

Artificial Cleaning

The technique for the patient is simple, but it must be carried out with the greatest thoroughness unattractive to most drinkers and is definitely harmful because the methyl alcohol it contains may cause blindness and even death, thus the use of methylated spirit in pharmacy is wisely limited by law, even for external applications There can be no doubt that from the points of view of revenue and the protection of the weaker brethren the introduction of methylated spirit has been a great success in Great Britain, though most laboratory workers and industrialists would welcome a supply of cheap ethyl alcohol which had not been denatured It is worthy of note that in this country where wines and spirits are fairly easily obtainable a highly poisonous industrial alcohol would therefore be drunk only by accident, and the Inland Revenue authorities have not seen fit to use anything more deadly than a small amount of wood naphtha and paraffin A complete denatured alcohol may also contain pyridine bases, pine oil, aniline oil, nitrobenzene, and orthonitrotoluene, whilst specially denatured alcohol may contain brucine salts when it is used for perfumes and toilet preparations In the United States the Commissioner of Internal Revenue insists that “every package of completely denatured alcohol containing less than 5 wine gallons” must bear under the skull and crossbones the following statement “Completely denatured alcohol is a violent poison It cannot be applied externally to human or animal tissues without serious injurious results It cannot be taken internally without inducing blindness and general physical decay, ultimately resulting in death” This terrifying statement might conceivably be regarded by some people as merely a rather lurid edition of the orthodox teetotal description of ordinary alcohol It appears that the liquids actually drunk in America are concoctions containing this denatured spirit—but not bearing this label Thus it is arguable that the Federal Government is to some extent responsible for accidents arising from the bootlegger's activities, because it insists that industrial alcohol shall be very poisonous but fails to prevent it from being disguised as whisky On the other hand, the Government may very well reply that any citizen drinks whisky at his own risk seeing that the taking of alcoholic liquor is against the law The risk of being poisoned in the United States, even by whisky which claims British origin, is so considerable that it must keep a large proportion of the population in the narrow path of abstinence Nevertheless, as we have already remarked, death is a drastic punishment for secret drinking

GASTRIC SECRETION IN GRAVES'S DISEASE

THE importance of the sympathetic in the pathogeny of Graves's disease is well recognised In our present issue we publish an article by Dr Henry Moll and Dr R A M Scott incorporating the results of their observations on the secretion of the stomach in this disease In 50 cases of hyperthyroidism, of which 34 were frankly Graves's disease, they found 22 cases of complete achlorhydria and 15 of marked hypochlorhydria, the deficient secretion being found almost entirely amongst those with true Graves's disease They found further that in such cases the rate of gastric emptying was exceedingly rapid, so rapid indeed, that very little was to be found in the stomach at the end of a quarter of an hour Discussing the causation of these findings the authors state that three possible explanations present themselves: First there is the possibility that a gastritis is the cause of the deficient secretion, but this is ruled out by the absence of any excess of mucus Next they discuss regurgitation of duodenal contents, chloride estimations give some support to this hypothesis, but only in a few cases, and it may be pointed out that complete achlorhydria from such a cause has never been observed, it being very doubtful if any reflux of alkali could keep the secretion of a normal stomach permanently neutralised Finally, they discuss the importance of inhibition of secretion by the sympathetic This seems to be the probable explanation R Gaultier has satisfactorily demonstrated the excessive secretion resulting from section of the splanchnic nerve; Izod Bennett and J F Venables have shown the inhibitory effect of emotions such as fear and nausea in man, and there is in general a mass of evidence pointing to the antagonistic effects on gastric secretion of the vagus and sympathetic nerves The interesting observations of Moll and Scott provide new evidence of sympathetic action

THE LEGIBILITY OF PRINT

THE printed word has only one function—to be legible Designers of type cannot be acquitted of a bias towards ornament or at least towards æsthetic arrangement, and the evolution of printing has not been governed wholly by the principle that the most useful shall survive It is not impossible, therefore that certain forms of type now in frequent use are ill-suited to their purpose and by their illegibility place an unnecessary strain on the eyes of countless readers In 1923 the Medical Research Council appointed a committee to organise and direct research into the legibility of printed matter, the committee consisted of Sir John Parsons, F R S, Mr F C Bartlett, Dr H Hartridge, F R S, Mr L A Legros, Mr D R Wilson, and Mr E Schuster, D Sc Their scheme of investigation was entrusted to Mr R L Pyke, who has been carrying out work in Mr Bartlett's laboratory at Cambridge and has written a report[1] which has now been issued by the Council At first sight the problem seems to present few difficulties but Mr Pyke's excellent review of previous work shows at once that it is exceedingly complex The first stumbling-block is the definition of legibility, which few investigators have attempted, some have ignored the fact that legibility refers to the act of reading performed under normal conditions Properly speaking a legible type is one that can be read easily under these conditions, but, as Mr. Pyke says “does ‘easily’ mean accurately, or rapidly, or both? or does it mean with little effort, and if so, does that mean without eye-strain or without fatigue (both the latter involve some reference to an extended duration in time, accuracy and rapidity do not)?” This suggestion of difficulty in definition is, perhaps, enough to give an indication of the many different criteria which investigators may consciously or unconsciously adopt These criteria may be objective, subjective, or functional, and in studying legibility in the light of subjective and functional tests the psychological and physiological variations of the human subject are a source of error which is exceedingly hard to eliminate It would be impossible to give a brief and accurate description of the problems which arose during Mr Pyke's investigation and of the means which he used to solve them, it is enough to say that they are admirably set out in his report Experiment was made with a series of eight types and the conclusion was reached that one of these (Lanston standard old style) was probably the most legible, whilst another (Lanston modern condensed) was probably the least But the reservation is made that these conclusions were true in the laboratory only, and Mr Pyke is very doubtful whether the relative legibility would hold in the ordinary world He puts forward the hypothesis, not unacceptable to the uninformed intelligence, that extremely large typographical differences must be present before it is possible to say that there is any difference in the objective legibility of types “Of types more slightly differentiated,” he remarks, “it is impossible to say that one is objectively more legible than another Such types will be ‘legible’ according as they suit the psychological make-up of the reader Hence, the most legible type, in this subjective sense, is unlikely to be the same for all readers These two ideas—that

A REVIEW OF RECENT WORK ON MEASLES *

By J E. McCartney, M D D Sc Edin.
DIRECTOR OF RESEARCH AND PATHOLOGICAL SERVICES, METROPOLITAN ASYLUMS BOARD

The recent decision of the Metropolitan Asylums Board to allot more beds in its infectious hospitals to measles has focused attention on the high death-rate for which this disease and its complications are responsible Work has been actively progressing in attempts to protect contacts against the infection and also to try and ascertain the causal agent of disease It is therefore opportune to review the recent work on measles to ascertain how far we have progressed in the fight against this important and serious menace It is not possible or profitable to refer to all the published work on measles that has recently appeared neither in the time at my disposal am I able to discuss fully all the points that I shall raise I give, therefore, the main facts and conclusions as they appeal to me particularly from the laboratory standpoint, knowing full well that they will not be universally accepted

The beneficial results that have been reported from the use of human convalescent serum and the announcement from the continent that an animal serum can be prepared which acts similarly have raised hopes that there is now some means of preventing an outbreak of measles in schools and other institutions The search for the ætiological agent of the disease has been vigorously carried out in recent years and three independent groups of observers have put forward claims for as many types of organisms each of which has been thought to be the causal agent of measles I shall endeavour as far as possible to assess the various claims that have been made and the conclusions reached and shall refer only to the important papers.

It will be convenient to review the recent work on measles under three headings. (1) The use of human convalescent serum; (2) the use of animal serum (Degkwitz) · (3) the various organisms claimed to be the causal agent of measles · (a) Caronia's organism, (b) Tunnicliff s diplococcus: (c) Ferry and Fisher s streptococcus

The Use of Human Convalescent Serum

Nicolle and Conseil [1] in 1918 first published results on the injection of serum from convalescents to immunise children who had been in contact with the disease Park and Zingher [2] in 1916 injected 41 children recently exposed to measles

Since that time numerous observers—Richardson and Connor [3] Degkwitz [4] Zimmermann [5] Blackfan and colleagues [6] Zingher [7] Debré and Ravina [8] Davis [9] Brügger [10] Weaver and Crooks [11] Park and Freeman [12] Haas and Blum [13]—have published results and all agree as to the efficacy of human convalescent serum if taken during convalescence and injected in adequate amounts shortly after exposure to infection By this means an epidemic may be cut short at once Other observers as suggested by Debre and Ravina,[8] use the serum to modify the disease to a very mild form, thereby inducing an active immunity

In the United States Park and Zingher [2] [7] have contributed greatly to our knowledge while on the continent Degkwitz [4] in Munich has recorded the results obtained in more than 1000 cases in 1921 and 1922

The numerous observations reported may briefly be summarised as follows —

> Six c cm of serum for children under 3 years of age and 6 to 10 c cm for children over 3 years are sufficient to protect from measles if injected within five days of exposure
>
> Inoculation on the seventh day is uncertain and on the eighth day does not usually protect at all, although if the disease does appear it is in a very mild form and complications are not likely to occur

The prompt use of the serum will prevent an outbreak from spreading and thus obviate the cases of broncho-pneumonia which have such a distressing mortality.

The immunity conferred by the serum is, of course only passive and lasts from two to four weeks After that time the child becomes susceptible again to the disease The blood should be drawn from convalescents shortly after the temperature returns to normal. 7 to 11 days being advocated by some observers Antibodies are still abundant in the blood three months after convalescence but they are considerably reduced in amount The serum can be stored in the cold for many months without losing its potency.

The method advocated by Park [12] for obtaining blood is as follows

> Adults preferably are used The blood is taken from the arm vein and run into a 500 c cm bottle containing 20 c cm. of 25 per cent sodium citrate and 0 3 g (equals a final dilution of 1 in 1500) of oxyquinolin sulphate (chinosol) as a preservative The red cells are allowed to settle by gravity in the ice box or are thrown down by centrifuging, and the supernatant plasma is pipetted off and put up in 3 c cm. and 6 c.cm. ampoules and in 30 c cm. bottles
>
> Blood for the *Wassermann test* is taken at the time of bleeding and a sterility control made of the plasma at the time of bottling A positive Wassermann reaction or contamination of the plasma results in the rejection of the sample

Modinos [14] of Alexandria in view of the difficulty of obtaining blood from small children, advocates the use of a blistering agent, and can obtain 20 c cm of serum from blister fluids. He states that children are less liable to be suffering from syphilis or tuberculosis than adults and that he has never known malarial parasites to be present in the fluid

The value of convalescent serum has been definitely proved Given in adequate doses and shortly after exposure to infection it will prevent the onset of the disease and is of immense value in stopping an outbreak, particularly where a large number of susceptible individuals are congregated together as in schools and orphan asylums Even if the serum is given in smaller doses or at a later date after exposure to infection the disease is greatly modified and is mild in character The rise of temperature is very slight, rarely to 100° or 101° F. Koplik spots are few or even absent, the coryza is slight, and the rash less severe There is practically no danger of complications and the recovery is certain and rapid The immunity from such an attack is active and lasting [15]

Cowley,[16] in an outbreak in an institution did not have enough convalescent serum to prevent the disease from spreading but allowed the epidemic to run its course treating each case of the disease when it occurred with serum from a convalescent 3 c cm were ordinarily administered and 5 c cm if the case was severe The disease was considerably modified, the temperature being quickly lowered, and there were no serious complications

Serum taken three to four months after convalescence has an effect in modifying the disease while blood from adults who have had measles in infancy, though not preventing infection will to some extent render the disease less severe One of the problems in the use of measles convalescent serum is the difficulty of obtaining a continuous supply of blood sufficient to meet the demands of large cities and institutions The serum can be taken in practicable amounts only from adults and the number of these taking the disease is comparatively small and not all are willing to have blood removed This difficulty will always remain, and in Budapest the mayor of the city has appealed to adult convalescents to give a suitable amount of blood Another objection raised has been the

---

* Based on a paper read before the Society of Medical Officers of Health (Fever Group) on Oct. 22nd, 1926

A small tooth-brush—soft at first later medium hard, but never very hard—with discrete tufts of bristles set in serrated rows is used to carry the paste as far as possible on wall surfaces of the teeth, then a piece of dental floss silk or 3-ply worsted is taken and passed through the interdental spaces to clean them with the paste and remove all foreign matter This done, the teeth are finally vigorously brushed Twice a day, before retiring and after breakfast, is usually sufficient, but after every meal is ideal A mouth-wash before breakfast is usually sufficient It is of little use to employ an elaborate toilet immediately before a meal An ideal mouth-wash that can be used indefinitely is one containing carbolic acid 1 per cent and chlorate of potash 5 to 10 gr to the fluid ounce It is also advantageous to massage the gum gently with a soft brush wet with weak salt solution The paste or powder should consist of precipitated chalk containing 10 to 10 gr to the ounce of powdered soap and chlorate of potash

Misplacement of the third molars, upper and lower, and general crowding of the cheek teeth are the most important predisposing causes of pyorrhœa starting at the back of the mouth Mouth-breathing, and the crowding and misplacement of the anterior teeth associated with it, or arising independently, strongly predispose to pyorrhœa in the front of the mouth A most intractable gingivitis—usually hypertrophic—arises and speedily develops into pyorrhœa unless the mouth-breathing is stopped and the crowding and associated traumatic occlusion relieved

Intermediate Cases

It is with the intermediate cases of pyorrhœa that the greatest difficulties arise Two methods of treatment are adopted which vary in accordance with the general condition of the patient In those in which the disease can be considered a purely local one less drastic measures are employed than in those showing evidence of secondary infection In the first place there is usually a gingivitis sometimes running an acute course, but more commonly a chronic one, which may be (*a*) atrophic, producing marginal recession, (*b*) ulcerative, due to local irritation by seruminal calculus, or (*c*) hypertrophic, resulting in fibrous overgrowth of the gingival margin and interdental pupillæ This last type is very common and produces large superficial stagnation areas as the redundant tissue encroaches over the enamel In other cases, apart from a chronic œdema of the whole of the gum, there is no apparent gingivitis, but the pockets around the roots are deep and exude pus freely

The first step to take is to clean the mouth thoroughly There is usually food débris in the stagnation areas, and on the teeth themselves is a soft deposit of oral débris and accumulated secretions, and on the necks a ring of seruminal calculus Thorough scaling and polishing with the use of floss silk and an atomiser spray in the interdental spaces completes the first stage of the treatment, which is accompanied by a stricter oral toilet on the part of the patient and the use of a mouth-wash The next step is to remove certain teeth which cannot be made self-cleaning or even be adequately cleaned by artificial measures, the third molars are the ones most often concerned Of the remaining molars those in which the membrane has been destroyed to or beyond the bifurcation of the roots should be removed Radiographs of such cases always show the bony septum between the roots rarefied or completely absorbed at its tip, and such an area always forms a septic focus which cannot be obliterated Of the remaining teeth, again, those in which the pockets extend over one-third of the root, or those that are definitely loose should be removed This alone, accompanied by improved hygienic methods on the part of the patient, produces a very considerable improvement in the condition of the remaining teeth

The complete removal of all deposits at the necks and on the roots of the teeth exposed in the pockets checks suppuration Washing of the pockets, together with astringent massage of the gum, removes secretions, and by promoting a more normal blood flow relieves congestion Thus the depth of the pockets is reduced by shrinkage of the gum around them In this way the purulent discharge may be completely stopped and the gum tightened to such an extent around the necks of the teeth that ingress of foreign material is prevented The pockets do remain, however, although considerably less deep, and are certain to become reinfected sooner or later It is usual for a general deterioration to take place in the space of a few months and a complete relapse is only a matter of time if treatment is not repeated at very frequent intervals

Gingivectomy—A much more lasting result may be obtained by performing the operation of gingivectomy on teeth selected for retention, especially where a hypertrophic gingivitis is present After the teeth and gum margins have been thoroughly cleaned and the chronic stagnation relieved by massage and irrigation, the redundant gum is cut back to the necks, or beyond if the pockets go so far, under novocaine and adrenalin anæsthesia, given by local infiltration Healing soon occurs and if the parts are kept clean recurrences are not common, ordinary methods of cleaning being sufficient to prevent further stagnation Gingivectomy can also be performed where there is no marginal hypertrophy and where the pockets are entirely confined to the roots Radiographs should always be taken The most promising cases are those in which there is a sharply defined margin to the absorbed alveolus Under local novocaine and adrenalin infiltration a horizontal incision is made through the gums on the buccal aspect down to the cementum at the level of the absorbed alveolus to meet a similar incision on the internal aspect The loosened gum is then removed and the raw surfaces kept constantly washed until they heal In this way the pockets are obliterated, much larger spaces are left between individual teeth, and natural cleansing is thus promoted If kept perfectly clean by gentle swabbing with wool soaked in 5 vols peroxide of hydrogen and the daily use of the atomiser spray, the cut surfaces are readily covered by epithelium without the formation of any redundant tissue The main disadvantages are the somewhat unsightly appearance of the elongated teeth, and in some cases, the extreme irritability of the tooth pulp due to abnormal stimulation through the exposed cementum

Ionic medication should be employed in all cases, whether or not gingivectomy has been performed The use of a variety of astringent solutions in this way materially lessens congestion, checks abnormal secretion, and generally gives tone to the tissues, besides relieving the associated discomfort

Autogenous vaccines can be used with advantage when associated with energetic local treatment, but they are valueless without it In acute cases especially the results of local treatment are seen much more quickly than in those in which they are not employed The possibilities of general infection are rendered more remote and cured cases do not tend to relapse so readily

G B PRITCHARD, M R C S Eng, L D S,
Assistant Dental Surgeon, Guy's Hospital

PERTH ROYAL INFIRMARY MATERNITY UNIT—One of the first separate maternity wards to be erected in connexion with a hospital in Scotland is approaching completion at this institution It is the gift of Lord Forteviot, and contains 22 beds and the usual accessories

ENLARGEMENT OF GLASGOW HOSPITALS—It is hoped shortly to open a new wing of the Victoria Infirmary, consisting of 5 extra wards containing 105 beds and 15 cots The institution will then accommodate 380 patients, and the scheme includes two new operating theatres and an extension of the nurses' home The Royal Samaritan Hospital for Women is also being enlarged, and when the work is finished in March the number of beds will be increased from 90 to 160 Here, also, there will be two new operating theatres and an extension of the nurses' home The two enlargements will cost about £180,000 regarded as pathological I was unable to confirm any of Caronia's claims

Selma Meyer,[25] in attempting to repeat Caronia's work found the small bodies in uninoculated media and in cultures from chicken-pox, polyarthritis and normal blood Rabbits injected with uninoculated culture media showed bodies in the liver and spleen similar to those described by Caronia as being specific for scarlet fever and measles in animals The complement fixation reaction with the "cultures" and rabbit and human sera was not specific.

Meyer[26] injected 13 children with measles "cultures" prepared by Caronia, and also with a vaccine prepared by herself in exactly the same way as Caronia's material. The children were exposed to measles at periods of two to 15 days after the last injection All the children took the disease and the symptoms were equally typical and no less severe than in uninoculated children Regarding Caronia's claims to produce measles in children with his cultures, Meyer asked Sindoni (Caronia's assistant and co-author of several papers on measles) to inoculate two children with Caronia's own cultures while she (Meyer) also inoculated two children with "cultures" prepared by herself. None of the four children showed any symptoms Later three of the four children contracted measles spontaneously.

Takaki[27] cannot confirm Caronia's claims and thinks the alleged "micro-organisms" are due to the autolysis of the added animal organs. The cultures give non-specific results when used as antigen in complement fixation tests with measles convalescent serum. Takaki quotes Hektoen's results showing that minimal amounts of measles blood are infective and the so-called protective results of Caronia are due to the amount of blood in the cultures being sufficient to immunise

Szirmai and Jacobovics[28] cannot confirm any of Caronia's results.

De Villa inoculated Caronia's organism intradermally and produced a reaction in 65 per cent of children who had no history of measles He obtained no reaction in children vaccinated with cultures and in 75 per cent of children who had had measles.

On the available evidence therefore it would appear that none of Caronia's claims can be confirmed or justified

(*b*) *The Work of Tunnicliff.*—Within the last few years there has appeared a series of papers by Ruth Tunnicliff, of Chicago In 1917[29] she reported the isolation of a small round sometimes flattened, diplococcus occurring in short chains or in clumps which produced small green colonies on blood-agar. This organism was cultivated under strict anaerobic conditions from the throat secretion, but occasionally in the eye and nasal secretion taken in the eruptive and pre-eruptive stages of measles It has not been found in patients with fading measles eruptions or in diseases other than measles.

The primary cultures—i.e., from measles material will only develop on blood-agar under strict anaerobic conditions Growth occurs in five to 15 days usually about the ninth day, and the colonies are larger if glucose be added In subculture the organism grows under aerobic conditions It may then be grown on ordinary agar or in broth although the growth is scanty It ferments glucose and saccharose, and all strains but one ferment maltose. Mannite and lactose are occasionally fermented but never inulin salicin or raffinose The green-producing diplococcus is non-soluble in bile and does not liquify gelatin. The organism is *Gram-positive*. Recently isolated strains pass a Berkefeld N filter and the organism resists drying for 24 hours but not 48 It is easily killed by heat (45 minutes at 57° C.) but survives for 14 days at −0 2° C and for two months in 50 per cent glycerin In the early stages of the disease this diplococcus alone is found in the blood stream but at the height of the fever other organisms may also be isolated

Tunnicliff and Brown[30] later showed that opsonins for the diplococcus occurred in convalescent human serum and that complement-fixation tests showed a slight positive. Rabbits inoculated with the organism developed opsonins and agglutinins, the latter often in high titre. The agglutination tests is useful for identification but the organism tends to be auto-agglutinable.

Tunnicliff and Moody[31] attempted to transmit measles to animals Inoculation of monkeys with measles material produced, after eight days' incubation, a leucopænia and what were thought to be Koplik spots In one animal the inoculation protected against a subsequent injection of the diplococcus and in another of measles material

With guinea-pigs no definite results were obtained.

Experiments were carried out with 46 rabbits as follows: nine were inoculated intratracheally with measles material, 22 with diplococci, and 15 with control organisms

The authors thought they produced Koplik spots usually only one. About 85 per cent. of the animals showed a diffuse erythema or maculo-papular eruption which was never so marked as in human cases. The pathology of the Koplik spots produced was said to be similar to that of human cases described by other observers. Rabbits inoculated with the diplococcus are refractory to subsequent inoculations.

In connexion with the attempts to communicate measles to lower animals Nevin and Biltman[32] inoculated blood from measles patients into rabbits They claim that 33 per cent. of the rabbits showed Koplik spots and 100 per cent showed eruptions The authors state that the eruptions were not typical of measles but a general exanthem. The blood count and temperature are not reliable indications of experimental transmission of the disease.

Grund[33] injected nasopharyngeal secretions into rabbits He claims that 15 per cent show Koplik spots and 75 per cent. eruptions which are described as a diffuse punctate erythema with a maculo-papular rash

In contrast with the above results Purdy[34] was unable to find any evidence of transmission when measles material was inoculated into rabbits.

It is not possible to place reliance upon the above findings as the criteria of transmission on which the conclusions are drawn—namely, a general erythema and Koplik spots without other manifestations—cannot be termed reliable evidence of experimental measles, particularly with reference to the rabbit. It is well known to all laboratory workers who have used rabbits for experimental purposes that apparently normal uninoculated rabbits may show wide differences from the accepted average standards, particularly with reference to temperature and blood counts Observers are not all agreed that the transmission of measles to the rabbit has been accomplished

Tunnicliff[35] has attempted to find a skin reaction for measles analogous to the Dick test for scarlet fever An extracellular toxin was prepared, diluted 1 in 10, and injected intradermally It was found that only 50 per cent. of reactions were obtained in individuals who had no history of measles The toxin was neutralised by human convalescent serum and by immune goat serum, but not by normal goat serum As the extracellular toxin was not successful whole cultures were next tried. Young anaerobic cultures in dextrose ascitic fluid broth killed by 0 4 per cent phenol produced a skin reaction when injected undiluted into the shaved skin of the rabbit. This antigen is neutralised by convalescent human serum and by immune goat serum

For use on human beings the antigen was diluted so that no reaction was produced in individuals who had a history of measles At this strength (about 1 in 40) reactions were produced in persons not having had measles, but such reactions did not occur in measles patients after the rash nor in 96 per cent of persons who had had measles

Tunnicliff and Hoyne[36] immunised goats with cultures of the diplococcus. The serum was used to try to prevent the occurrence of measles in short period of immunity (two to four weeks) conferred by the injection, and after that time the child again becomes susceptible While the use of convalescent serum is not the ideal method for overcoming measles, it has a very great value particularly with young people. In children under 3 years of age measles is a very dangerous disease, and the longer the child manages to avoid the infection the less chance is there of complications ensuing when the disease does come If, therefore, convalescent serum will prevent a young child from becoming infected, it will carry him over a critical period of life to an age when the disease is likely to be less harmful

It is a debatable point as to the best way of using measles convalescent serum, whether to give large enough doses to prevent the onset of the disease, in which case the protection is only temporary until the passive immunity ceases, or to give sufficient merely to modify the form of the disease so that complications are reduced to a minimum and a lasting active immunity ensues It would appear that human convalescent serum is beneficial in any stage of the incubation as it will have, if not a protective, then a modifying effect, and its use is a powerful weapon in the hands of the clinician against the distressing mortality-rate

The Use of Animal Serum

Degkwitz,[17] of Munich, has produced from sheep a serum which he claims acts similarly to human convalescent serum Exact details as to the manufacture of this serum have not been published, but it would appear that sheep are repeatedly inoculated with filtrates of nasopharyngeal secretions from measles patients and with tissue cultures inoculated with measles "virus" No attempt is made to isolate a specific agent It is claimed that the serum from animals thus treated protects children exposed to measles. Degkwitz insists that the serum must be given on the fifth day of the rash of the child responsible for the infection The serum has been patented in this country and is manufactured on a commercial scale and advertised in Germany

The reports of the use of this serum have not, up to the present, been satisfactory

Kochmann[18] injected Degkwitz's serum into 19 children who had been exposed to measles Of these six did not contract measles, probably because they were already immune Of the remaining 13 who took measles, two died and one of these had been injected at the time stated by Degkwitz to be optimum Grave serum sickness occurred in one-third of the cases Kochmann considers Degkwitz's serum to be a complete failure

Kaupe[19] inoculated 18 children, of which three children had never had measles, while the remaining 15 had probable, though not certain, history of measles Injection was carried out as Degkwitz advised—namely, on the fifth day of the rash in the patient causing the infection The three susceptible children took typical measles, while four of the 15 others had serum sickness Kaupe advises against the use of Degkwitz's serum

Noeggerath, Oster, and Viethen[20] have tested Degkwitz's serum and state that it is without protective action if injected before infection If inoculated at the time advised by Degkwitz the serum seems to have an unfavourable effect They suggest that details of manufacture and testing the serum should be published and the serum taken off the market

Seligmann, Dingmann, and Alterthum[21] have used human convalescent serum with success in the Berlin Municipal Asylum for the Homeless and are in a position to compare Degkwitz's serum which they have tried They point out that it is often impracticable to adhere to Degkwitz's advice to inject his serum on a particular day of incubation, but in any case it does not matter as the serum does not protect

Recently, Degkwitz[22] states that his animal serum has only been withdrawn from advertising but not for sale He states that his instructions should be followed exactly and reports good results from various hospitals From the published results of the use of Degkwitz's serum it would appear that it is of no value Certainly the mystery in which its manufacture is shrouded, and the absence of any definite ætiological agent isolated, do not inspire any confidence in the finished product Until Degkwitz produces precise information as to the manufacture and testing of his serum and proves it to have a definite protective effect, it must be regarded as valueless in the prevention of measles infection

The Various Organisms Claimed to be the Causal Agent

(*a*) *Caronia's Organism*—In 1921-2-3 Caronia[23] published the results of his investigations into the causes of scarlet fever and measles His claims with regard to the latter disease may be summarised as follows —

> In Tarozzi-Noguchi media under anaerobic conditions there can be cultivated from the blood, bone-marrow, filtrate of nasopharyngeal secretion and cerebro-spinal fluid of children in the prodromal or rash stages of measles small Gram-negative micro-organisms, round in shape and arranged in pairs like diplococci Similar micro organisms can be demonstrated microscopically in the bone-marrow and in the conjunctival and naso pharyngeal secretions The serum of measles patients, especially in the rash stage and in convalescence, contains agglutinins, amboceptors, and opsonins specific to these organisms

Caronia claims to be able to produce a disease resembling measles in young rabbits by intravenous inoculation with blood from measles patients From the blood of the animals thus infected the micro organisms can be isolated and at a later date specific antibodies are found The intravenous injection of large doses of the micro-organism into young rabbits produces a disease similar to measles and which sometimes causes a fatal issue The infected animals are said to show serological and cultural characteristics very similar to those in the human disease

Caronia has attempted to immunise healthy children as a prophylactic measure with inactivated or weak cultures He claims to produce immunity to measles without any reaction Furthermore, Caronia states that the repeated inoculation of healthy children with large doses of cultures of the micro-organism produces a slight but typical form of measles Caronia's claims, however, have not been verified

Shortly after Caronia's original paper appeared I attempted to repeat the work Numerous modifications of Noguchi media were tried, ascitic fluid ascitic fluid and broth, broth, human serum, sheep serum, rabbit serum, with and without pieces of fresh rabbit kidney, and pieces of sterile potato Blood and filtered nasal washings from patients in the prodromal and early rash stages of measles were inoculated into the various media and incubated for periods up to one month In no instance could any definite organismal structures be found Films from these cultures stained with Giemsa's stain showed minute round bodies just on the limits of visibility (using a 2 mm apochromatic lens) and which to the inexperienced might be regarded as organisms Similar bodies, however, can be demonstrated in the control uninoculated tubes which have been similarly incubated and stained These minute bodies, which are protein particles, are to be found in media rich in protein and are probably caused by alterations in the hydrogen-ion concentration They have no bacteriological significance whatsoever and their presence has on more than one occasion led observers to draw erroneous conclusions regarding the ætiology of certain diseases[24]

I was unsuccessful in obtaining anything which could be regarded as a viable multiplying organism Experiments on the inoculation of rabbits with blood and filtered nasal secretions were also entirely negative There were no changes in the leucocytes, temperature, weight or condition of the animal which could be that the conclusions are justified from the evidence brought forward

Conclusion

In this review I have attempted to assess some of the recent work on measles as the facts and conclusions appeal to me The problem of the ætiology of measles has not yet been solved and more critical and convincing experiments are required The work reviewed above is a step in the right direction and it is gratifying to know that active research is being carried out by numerous workers in many different countries Summarising, therefore convalescent serum has a very definite prophylactic and also therapeutic value, but owing to the difficulties of obtaining an adequate and constant supply its use is limited Up to the present the reports on the uses of Degkwitz's serum have not indicated that it has any specific value With regard to the claims of various observers concerning the causal agent of measles, the work of Tunnicliff in my opinion. deserves consideration

INDUSTRIAL RHEUMATISM

PROPOSED CLINIC IN LONDON

THE following memorandum, issued on behalf of a subcommittee of the International Society of Medical Hydrology gives a brief outline of the extent and nature of industrial rheumatism and suggests principles for its treatment at a clinic in London

Incidence and Causation

The information now available as to the prevalence of rheumatic diseases among industrial workers ("industrial rheumatism") reveals a remarkably uniform incidence in northern European countries It appears that "rheumatic diseases" (as defined by the British Ministry of Health) are accountable for about one-sixth of the total invalidity of insured persons in England Sweden Norway, and Denmark Next to the infirmities of age arthritis alone is regarded in Sweden as the most serious cause of disablement As regards the incidence of the different forms of rheumatic disease the British report[1] shows that out of 20 cases six may—roughly speaking—be described as lumbago four muscular rheumatism two sciatica or brachial neuralgia two rheumatoid arthritis. two osteoarthritis two subacute rheumatism, one rheumatic fever. and one gout But. although arthritis is accountable for only a small numerical minority of rheumatic cases the invalidity arising from arthritis is 'tedious painful, and costly," and actually causes as much incapacity for work, and, therefore. economic and financial loss as muscular rheumatism fibrositis, lumbago and sciatica combined

Like rheumatic fever and subacute rheumatism. chronic rheumatic affections of the joints and soft tissues are caused (in part) by climatic influences. Damp houses, the proximity of underground streams, certain localities and aspects, seasons of the year and types of weather increase the incidence of all these diseases They are much less prevalent in dry, warm climates Focal infection has been demonstrated in very many cases of arthritis, but the body may habitually give lodgment to many kinds of possibly-infective organisms Chilling of the body is one of the chief determining causes which enable these specific causes or agents to become infective. For this reason chill ranks high in cold and temperate climates as a cause of disease—rheumatic, catarrhal. tuberculous &c Habit and occupation are also determining factors and Dr. van Breemen has said that "every occupation has its own rheumatism

Need for Extended Facilities for Treatment

The inability of the spas to deal adequately with the vast number of rheumatic cases that require hydrotherapeutic treatment renders it essential that more extended facilities of this nature be made available There is an urgent need for centres of physical treatment in the large centres of population, such as already exist in continental towns In Berlin Dresden. Hanover, Vienna Amsterdam. &c. thousands of insured persons are treated near their own homes many of them coming for treatment after working hours The same methods are employed at the Bispebjerg Hospital in Copenhagen and at the Board of Pensions' institutions in Sweden. It may be noted that the curative value of diaphoretic drugs points to the activity of the skin as a normal avenue of relief in rheumatism and that heat is the most powerful of diaphoretics

On the preventive side it is to be hoped that pit-head baths and similar facilities for factory workers will be extended. If properly organised they will undoubtedly form an important aid in prophylaxis The efficacy of hot baths for the immediate relief of chill and over-fatigue was amply demonstrated in the war

The Ministry of Health has recently outlined a service for the medical care of industrial rheumatic cases including three different types of institution :—

"A *Physical Treatment Clinic* would serve as a clearing house-directing patients to the form and place of treatment best suited to their need, some to spa treatment, some for intensive study at an *arthritis unit* whilst others would be greatly benefited by treatment at the clinic itself These clinics would be out-patient institutions to supply those forms of physical treatment which are so often necessary for the children exposed to infection Only a few children (13 in all) were injected, and the results tended to show that the serum has no power to prevent measles if inoculated after the first two days following exposure They claim that the serum protects rabbits inoculated with measles diplococcus whereas controls treated with normal goat serum showed "symptoms characteristic of measles—viz , temperature, Koplik spots, and eruptions" If, however, the protocols of the experiment be analysed, it is found that one rabbit inoculated with an ascitic fluid broth culture of nasopharyngeal secretion had a rise of temperature of 2° F Another animal showed a rise of 1 3° and a faint eruption, while a third showed a temperature increase of 1° F and "Koplik spots"

---

[1] The Incidence of Rheumatic Diseases Ministry of Health 1924 It must be remembered that the Report refers only to insured persons Insured females in England and Wales do not afford a representative sample of the female population of the same class as the younger age groups are much over-represented, so many women falling out of insurance on marriage. A true sample would show a somewhat higher proportion of chronic arthritis cases.

These experiments are few in number and the evidence cited is no proof of experimental transmission A disadvantage of goat serum is its toxicity

Hoyne and Gasul [37] have given Tunnicliff's goat serum a more extended trial Forty-eight infants and children had been exposed to measles, and of these serum was given to 39 Of these 34 were completely protected, while in the other five only a mild form of the disease resulted No deaths or complications occurred and the temperature was not greatly elevated The incubation periods were 20, 33, 33, 8, and 16 days Of the nine contacts who did not receive serum, eight took typical measles resulting in two deaths Serum rashes, persisting one or two days, were noted in 15 per cent of all the cases The passive immunity conferred by the injection of the goat serum is stated to last from two to four days

Recently Tunnicliff and Hoyne,[39] using the same batch of immune goat serum as Hoyne and Gasul,[37] injected 105 persons with a negative history of measles, but subjected to a definite exposure to the disease All persons who received serum five days or more after exposure developed measles The serum prevented measles in 45 per cent of persons injected on the fourth day after contact with measles patients, and in 97 per cent of those who received it in the first three days after exposure From 4 to 6 c cm were injected and 12 per cent of persons showed serum reactions Measles in children receiving serum was often very mild, but no modification of the disease as described by Zingher [7] and Weaver and Crooks,[11] following the use of convalescent serum, was observed

These reports on the use of immune goat serum are encouraging and strengthen the claim of Tunnicliff that the green-producing diplococcus is the causal agent of measles

(c) *Ferry and Fisher's Streptococcus* —Ferry and Fisher,[38] working in Detroit, have isolated an organism the toxin of which they *claim is specific to* measles The organism, which was obtained from the blood of patients in the early stages of the disease, is a small Gram-positive *aerobic* green-producing diplococcus, appearing both in pairs and in chains and which produces a soluble extracellular toxin It differs from the organism described by Tunnicliff in that it is an aerobe growing luxuriantly in the presence of oxygen and "that it produces a soluble toxin specific to measles" The authors are so confident of their claim that they have named the organism "*Streptococcus morbilli*"

Toxin was made by growing the organism in glucose broth, which, on being passed through a Berkefeld "W" candle gave a toxin said to contain 5000 skin doses per c cm Ferry and Fisher state that they have proved the "specific relationship of this toxin to the disease and the ætiological relationship to measles of the organism from which it was obtained"

Analysis of their protocols, however, indicates that these sweeping claims are not altogether borne out by the experimental data. For example, they state "Persons with no histories of measles gave positive skin reactions on intracutaneous injections of 0 1 c cm of a 1 500 dilution of the toxin, showing that they were sensitive to the toxin" Out of 35 tests on persons giving no history of measles only 14 gave positive skin reactions to intracutaneous injections of the toxin That is, only 40 per cent gave a positive reaction, and on this result the above conclusion was reached Surely with a 60 per cent of negative reactions the very opposite could be stated with equal correctness The statement "persons giving positive *histories of measles did not react to intracutaneous injections of the toxin*" is based on 30 injections in children with no positives and in 30 adults with two positives One feels that these numbers are not sufficient to warrant so sweeping a conclusion. Ferry and Fisher state that "patients in the pre eruptive and early stages of the disease gave positive skin reactions to the toxin, while those in the later stages and especially convalescents, gave negative skin reactions" They naïvely add "in hospital practice it is almost impossible to find a case of measles in the pre-eruptive stage, but of 15 cases obtained as early as possible seven gave positive reactions and none of the late and convalescent cases, 24 in all. reacted to the toxin"

The statement that positive skin reactions occur in the pre-eruptive and early stages of the disease is based on only seven positives out of 15 cases—i e , less than half, coupled with an admittance that they have not tried out the test on patients in the pre-eruptive stage of the disease Their statement that "when mixed with convalescent serum the toxin will not produce a positive skin reaction in susceptible persons" is very much modified in the next sentence when they say "in most instances the reaction was negative" This is a very vague statement from which to draw so important a conclusion

Ferry and Fisher report that the toxin is neutralised by an antitoxin prepared from animals by the injection of toxin, and that when mixed with scarlet fever antitoxin or normal horse serum the toxin is not neutralised Persons showing positive skin reactions with the toxin were made to give negative reactions by injection of measles convalescent serum A person showing a positive skin test was made negative by the injection of serum from an animal immunised with the toxin As the test was only carried out on one person it is an interesting fact to record, but no definite conclusions can be drawn from a single experiment

The statement that "serum of measles convalescent patients agglutinates suspensions of measles streptococcus while negative serum does not" was based on an experiment in which serum, pooled from several convalescent cases, was tested with four strains of measles streptococcus Only two of the four strains were agglutinated although the serum was from several patients and, therefore, more likely to give a higher percentage of positive results, 50 per cent of failures does not warrant a *statement* which indicates 100 per cent of results

The authors also say that "intracutaneous injections of live cultures of our organism produced severe local infections surrounded by large areas of hyperæmia, which at times extended over the entire abdomen and back, appearing very much as a typical measles rash" Their account of the protocols on which this definite statement is based is as follows "About 0 1 c cm of broth culture was injected intracutaneously and within two days there appeared a large raised area, about 4 cm in diameter, which next day resulted in an abscess with sloughing One rabbit showed a distinct redness over the entire abdomen and back while others were more or less hyperæmic" As a living culture of streptococcus was used, it is not surprising to learn that there was an abscess with sloughing "Distinct redness of the abdomen and back" cannot seriously be construed into a "typical measles rash" Similar results would have been obtained if any other virulent streptococcus had been used Similarly, killed cultures would also produce severe inflammatory reaction with the formation of a sterile abscess The work of Ferry and Fisher is described as a preliminary report and doubtless full details will shortly be available From the point of view of the laboratory worker, I do not think received 5000 mg -hours of radium, has been free for nine years, whilst the other two, aged 59 and 72, were operated on four and a half and four years ago respectively. Of three other cases treated in the same way two have died from intercurrent diseases and the third cannot be traced The patient treated with the excessive dose developed a late necrosis of the bone over an area the size of a shilling. In view of this sequela Dr Hofer and Dr Kofler resolved to decrease the dose to 3500 mg -hours in continuo and with this dose no untoward results have been noted As the prognosis is extremely bad in all cases of oral and nasal cancer these results are very remarkable and gratifying.

On behalf of the Senate the Rector of the University of Vienna has lodged a formal protest with the Ministry of Education against the conferment of the title of professor on Dr J. Bonvicini and Dr R Bauer The titles were given without the advice and presentation of the medical faculty of the University, and the incident. though in itself unusual, well shows what impossible conditions prevail in the University as regards the titles of professor or docent Though the latter rank is not very closely protected, the coveted title of professor is seldom recommended without long deliberation by the Academic Senate, three or four men being presented as candidates for each post As a rule the Ministry of Education falls in with the suggestions of the Senate, but it is not absolutely bound to do so

Dr Arnold Durig, professor of physiology in the University of Vienna, has recently been invited, for the fourth time, to occupy the chair of physiology at Berlin In spite of the very tempting offers, however. he has again decided to remain in Vienna, though the remuneration offered by the Austrian Ministry of Education is relatively small. His attitude has given great satisfaction to the Viennese students by whom his ability as a teacher is fully appreciated. and this satisfaction is shared by all who recognise in him one of the leading physiologists of Europe.

PARIS

(FROM OUR OWN CORRESPONDENTS)

The Recent Census

THE census returns have just been published, and it is found that of a total of 40 743 000 inhabitants of France 2,500 000 are foreign In the department of the Seine, which includes Paris, foreigners constitute 10 per cent of the population. The large influx into France is a source of anxiety to many economists who hold that immigration should be limited and that artificial conditions of monetary exchange should be corrected without delay. In the department of the Seine applicants for naturalisation will in future have to undergo a medical examination

Testicular Grafts

E Retterer has lately presented to the Societe de Biologie a description of the changes occurring in a simian testicular graft implanted in human testicle three and a half years ago , a second graft was made when the remains of the original graft were removed for examination It was found that tubules of epithelial cells were becoming converted into fibrous cords and that the portion of intertubular masses lying next the tubules was reticular in structure regions more remote being transformed into a mucoid tissue The epithelial elements of testicular grafts become slowly converted into fibrous tissue, the internal secretion supplied by the graft remaining active only as long as the epithelium survives

Remuneration of Medical Practice

Just at present certain medical fees in France cannot be demanded without some difficulty, because efforts are constantly being made by the State and by social insurance organisations to lower them. Official agencies of this kind offer very small remuneration for the treatment of war pensioners and cases of occupational sickness and accident The result is that many prominent medical men refuse to treat any cases of this kind, protesting that the fees offered do not allow them to maintain a respectable professional existence The tendency described, together with a movement, seemingly extending, towards general utilisation of public hospitals by persons amply able to pay for professional service, is adding seriously to the burdens borne by the French physicians

Medical Examinations

As already mentioned, a recent decree of the Faculte de Médecine made it necessary for candidates who had been rejected in one part of a medical examination to sit again—at the end of a year—for the whole examination, unless they had been able to secure a general average of 70 per cent of the possible marks The sudden introduction of this rule meant that many students would unexpectedly have to spend an extra year before qualification, and the National Union of Students' Associations protested vigorously to the Ministry of Education The Ministry has accordingly decided to suspend the new decree during the present scholastic year.

Prof A Pinard and his associates are bringing before the Chamber of Deputies a Bill making the presentation of a medical certificate, attesting the absence of contagious disease, obligatory for the legalisation of marriage

At a meeting of the Academie de Medecine on Dec. 28th Prof J Camus laid stress on the importance of preventing entry of small-pox into France. especially from Algeria Arabs from that country have recently been responsible for epidemics at Paris. Douai Valence, and other French towns During the past three months a number of cases have been isolated in Paris at the St. Louis Hospital and conspicuous municipal posters advise resort to the free vaccination stations

On Christmas Eve Prof Leon Bernard. of the Faculte de Medecine, was severely injured in a motor accident His condition is stated to be improving

MEDICINE AND THE LAW.

The Witness for the Crown

THE Leigh and District Medical Society passed last month a resolution recording its opinion that " in cases where criminal proceedings are instituted against medical men expert evidence should be obtained by the Home Office from men specially competent to deal with the department of medicine. surgery, gynæcology, or other special subject concerned " The resolution is understood to be a sequel to the recent criminal proceedings at Manchester Assizes where two medical practitioners were acquitted on a charge of manslaughter It will be recalled that an important question of fact for the jury to decide was whether or no there had been an illegal operation upon the dead woman Upon this issue Sir Bernard Spilsbury was called by the Crown to state the result of his examination of the body and to express his opinion how far what he found was consistent or inconsistent with the allegation of criminal abortion. His evidence and especially his inferences met with a vigorous challenge from gynæcologists and other specialist practitioners called on behalf of the other side . and the defence invited the jury to remember that the expert called by the Crown possessed no special knowledge or experience of gynæcology and that therefore his evidence had the less weight. The principle now put forward in the Leigh Society s resolution if endorsed by the medical profession generally. will doubtless engage the attention of the re-education of muscles and joints, and generally for the after-treatment of these diseases when the active stage has passed. They should be organised in close coöperation with an arthritis unit and with *the spa hospitals*, and provide continued supervision, observation, and after-care, following institutional treatment. Such clinics would be also of great service in diseases and conditions other than rheumatism, such as fractures, deformities, and diseases of the nervous system."[2]

As the physical clinic is the first link in the chain and should suffice for the immediate treatment of large numbers of cases, it is desirable to define its precise character, objects, and methods.

Proposed Physical Clinic in London.

(1) The basis of the treatment at the clinic, primarily for rheumatic cases, is heat and light, combined with movement and manipulation. It is held that both heat and movement are best conveyed to the body in water and that the manipulation bath is especially suitable for rheumatic cases. Hot air, vapour and electrical stimulation are valuable adjuncts. Great importance is attached to the sequence of physical impressions.

(2) The object of moist heat, manipulation, &c., is to relieve pain, stiffness and swelling, by a sedative action on the nerve centres and by increasing the blood and lymph circulation.

(3) A complete or combined physical treatment consists in a combination of two or more of the following procedures: (*a*) Either a hot manipulation pool or local bath (whirlpool, hot air, &c.) or dry manipulation; (*b*) a warm sedative pool, similar to the war-time pools; (*c*) light baths; (*d*) stimulant douches and friction baths; (*e*) remedial exercises; (*f*) electrical stimulation.

(4) It should go without saying that the clinic must be under the direction of a medical man who has had special experience in the various forms of treatment employed. Other necessary features are full clinical investigation and classification of cases, measurements of disability, records of treatment employed and reactions produced, tabulation of results.

(5) It is believed that a clinic of this character can be used: (*a*) For systematic preventive treatment in chill and over-fatigue; (*b*) in all apyrexial rheumatic diseases, both of the joints and soft tissues, accompanied by pain, stiffness, and swelling; (*c*) in many pyrexial cases, after the fever has subsided; (*d*) for periodical alleviation of incurable cases so as to enable arthritic persons in particular to continue in their occupations; (*e*) for non-rheumatic cases, cardiovascular or nervous, &c., for which physical treatment is indicated.

(6) It is proposed to establish in London a physical clinic on these lines for insured rheumatic persons. A minimum of 200 cases per day is regarded as an economic unit, the installation to be arranged so as to be capable of dealing with 400 cases per day. It is intended that the work of the clinic should be carried on in full cooperation with research work, with surgical and orthopædic hospital departments, and with the spa hospitals.

This memorandum is signed by Dr R. Fortescue Fox, Dr R. L. J. Llewellyn, and Dr M. B. Ray.

VIENNA

(FROM OUR OWN CORRESPONDENT.)

The Sick-Clubs and their Doctors.

AN unpleasant surprise has been sprung on the profession by the Government. Everyone in Vienna who works for wages—that is to say, everyone who receives regular weekly or monthly payment—is obliged to belong to one of the three large institutions (*Krankenkassa*) which provide free medical aid and sick pay for their members, and in each of the provinces there are two or three large and independent institutions of the same kind. Such is the political condition of this country that most of these institutes have elected Social Democrats to their managing boards, and as the electorate is very evenly divided between the Social Democrats and their reactionary opponents, the Christian Socialists, many people have found themselves, against their will, in Socialist institutes. The Government has now attempted to break the supremacy of the Socialists in the *Krankenkassa* by bringing before Parliament an Act enabling the formation of new sick-clubs, to be called *Wahlkassen*, or alternative clubs. The plan is that everyone shall be allowed to choose the institution to which he shall belong, and any body of 1500 members will be entitled to form a new club. This means that the old-established sick-clubs—with anything from 50,000 to 180,000 members each—will be broken up, numerous small clubs suddenly appearing in their stead. Naturally the interests of the doctors and the patients cannot be served by such small organisations. Whereas the funds accumulated by the big institutes insure both patients and doctors against undue risks and guarantee their fees and old age pensions, the small number of members of the new clubs means an increased risk of morbidity and a loss of all guarantee. It is recognised by all insurance companies that the broader the base—i.e., the bigger the numbers of members—the less the risk of failure. But here the Government is working in the face of this principle; it is going to narrow the base, and thus increase the risks. If the big institutions lose members they will have to dismiss doctors, and this will mean unemployment for a certain number of medical men whose only source of income is their work for the sick-clubs. But what causes even more annoyance is the fact that the Government—or rather the political parties forming it—have worked out their scheme without so much as asking the opinion of the profession, which has simply been faced with a fait accompli. There cannot, however, be any sick-clubs without doctors, and as unanimous repudiation of the *Wahlkassen* was expressed at several mass meetings last week, there are strong reasons for hoping that the plan will come to nothing. The public, or rather the prospective members of the clubs, are also able to understand that a large, powerful, well-established, and rich organisation is much better able to look after its members than a new, poor, and small body.

Whilst I was writing this, news reached the leaders of the profession that the Government intends to meet the demands of medical men by laying down in the Act the principle that all the rights of doctors serving the existing clubs must be secured before any branch club is brought into being. The profession has therefore resolved for the present not to carry out its threat of a medical strike, and is adopting the policy of "wait and see."

Cancer of the Nose.

At a recent meeting of the Vienna Medical Society Dr G. Hofer demonstrated four patients who have remained cured for long periods after operation for nasal cancer. Working in cooperation with Dr Kofler, he discarded the methods previously used in treating malignant disease of the nose, and resolved to remove all the diseased tissue, commencing with an incision above the orbit or at the fossa canina or approaching the nasal structures with Langenbeck's incision, according to the situation of the tumour. The entire mucous membrane of the nose and the accessory sinuses are removed and operation is immediately followed by application of a large dose of radium, which is well borne by the nasal tissues. Dr Hofer now uses very big doses—viz., 2900–3500 mg.-hours in continuo. Cancer of the nose has long been regarded as an absolutely fatal disease and statistics show that until 1914 only 2 per cent. of patients remained free from recurrence a year after operation. The metastatic growths are late, but local recurrence is very common. Of the four patients demonstrated by Dr Hofer and Dr Kofler, one, who is 68 years old, has had no return of the growth during nine and a half years; another, aged 67, who plan is obviously an advance It is part of a general movement throughout the world towards efficient port sanitation and simpler quarantine procedure The port medical services employ few officers, but are immensely important. every year an enormous amount of work has to be done to prevent the admittance of infectious disease into this country from abroad Some idea of the scope of the work may be gleaned from the following summaries of activity at Liverpool and Bristol during 1925

---

[2] THE LANCET, Nov. 6th, 1926.

Port of Liverpool

Dr A. A. Mussen mentions that 6650 inspections of ships were made and 995 had nuisances on board, more in the foreign-going than in the coastwise section, more in British than in foreign ships To prevent the importation of infectious disease, ships from ports deemed infected and ships with known infectious disease on board are visited before docking by an assistant medical officer, all ships are visited by a sanitary inspector as soon as possible after docking, and everything possible is done to diminish rats and to find plague infection amongst them at once should it arise. It is now under consideration whether captains should not report by wireless if they have cases of sickness on board, in order that all such ships may be visited by a medical officer During the year 191 cases of infectious disease were landed at Liverpool, among them one case of small-pox was found in an outward-going steamer; 13 cases of typhoid fever, 4 of paratyphoid, 19 of malaria, 64 of tuberculosis (the majority were passengers), and 5 cases of anthrax occurred in the area Rat plague, apt to remain long latent is always being sought in ships, by inspection, by careful sampling of the rats all over the ship, by watching for dead or sick rats during cargo discharge, and on the docks. by trapping and preventing harbourage by quick removal of refuse, by cleanliness, and by raising temporary wooden offices 18 in. above the ground. Dead rats are examined by the city bacteriologist for plague, but it was not found in any case in this year Fumigation of a ship is asked for if many rats are found; it is rarely necessary to fumigate every six months Much may be done when a ship is building towards making her ratproof: a new improved rat-guard for hawsers, devised by Dr C F. White (The Lancet, 1925 i. 695), has found approval Fumigation was done on 112 ships with SO_2, in 21 with HCN, in every case the whole ship being fumigated at one operation. Fewer rats were caught this year than last, the reward, we may hope, of perseverance On ships 11,088 rats and mice were caught by the official rat-catcher from the quays 2508 In all 61,117 rats were taken at 13,000 visits in the port and the city, and as usual nearly all those caught on board were black; most of those on the quays and in the warehouses were black, but in the sewers there was hardly a black rat, almost all were brown The Minister of Health visited the port and was shown the methods of killing rats and fleas including the methods of fumigation Zyklon, a mixture of 97 5 per cent of hydrocyanic acid with 2 5 per cent tear gas, soaked up in kieselguhr, is reported very effective in concentration of 0 15 per cent HCN for two hours Thorough after-ventilation is essential, and the tear gas is not thought to be a complete safeguard At the city clinics for venereal cases there were 2386 new cases, at the Seamen's Dispensary 1084; total attendances were 43,359 and 27 265, which seems to suggest that the seamen attended more persistently Of every seven cases two were syphilis, one soft chancre, and four gonorrhœa Ships are said to be cleaner than formerly, sanitary fittings are better and better respected, and the men complain more readily of infestations Yet more nuisances are reported this year than in 1924—2701 dirty forecastles and 681 foul water-closets Aliens to the number of 21 613 were inspected and 10 certificates of rejection issued A medical inspection room is wanted. Verminous emigrants were dealt with at the city hospitals Meat inspection is much simplified under the new regulations 1192 tons of meat were condemned as brine-stained or decomposed, and destroyed or released for industrial processes; similarly 845 tons of fruit and 6085 tons of cereals Cheese in a closed hold for six days caused CO_2 poisoning of two men who recovered; preliminary ventilation will be done in future. All second-class and steerage passengers outward bound are inspected by the Board of Trade, and all crews on ships going to America An inspector of the Port Sanitary Authority attends these inspections to supervise the removal of all who are rejected for actual or suspected infectious disease In 231 inspections 23 persons were rejected—5 for measles, 4 for scabies Three cases of trachoma were found in transmigrants

Port of Bristol

Dr D S Davies reports that Bristol Port lost her launch by sale in 1912, and her port hospital ship by collision in 1916, and that neither has been replaced Infected and suspected ships are visited in the roads by a hired tug, other ships are visited on arrival in the docks by the sanitary inspector. If there are infectious cases on board or if the ship comes from infected ports the medical officer is informed and visits Cases are then removed to the city hospitals, disinfection and other necessary measures being carried out. In 1925 20 cases of infectious disease were dealt with—8 of malaria, 6 of enteric fever, and 3 of tuberculosis Four cases of beri-beri, in Indians from Australia were sent to the Royal Infirmary. and 2 cases of (tertian) malaria to Ham Green Hospital The assistant medical officer performs duties under the Dangerous Drugs Act. During the year 2267 ships were inspected, 34 ships were fumigated, 1 with HCN (no rats), and 33 with sulphur (35 rats per ship); 11,626 rats were caught or found dead, about one-fifth on ships, 116 of these were examined, but no plague rats found. The chief defects on ships were dirty forecastles and foul closets 191 (8 4 per cent) ships had defects, more numerous in foreign (10 5) than in coastwise (3 7) ships, and in foreign-owned (8 5) than in British (8 2) steamers 2225 dirty or infected beds were destroyed One ton of meat, 11 tons flour, 20 tons wheat, and 21 tons of fruit and vegetables were destroyed

---

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC 25TH 1926

Notifications—The following cases of infectious disease were notified during the week. Small-pox, 302 (last week 315); scarlet fever, 1314, diphtheria, 1056, enteric fever, 30; pneumonia, 1173; puerperal fever, 39; puerperal pyrexia, 104, cerebro-spinal fever, 7, acute poliomyelitis, 23; acute polio-encephalitis, 6, encephalitis lethargica, 29; dysentery, 14 ophthalmia neonatorum, 100 There was no case of cholera, plague or typhus fever notified during the week.

Deaths—In the aggregate of great towns, including London, there was no death from small-pox, 4 (0) from enteric fever, 14 (0) from measles 9 (0) from scarlet fever, 39 (16) from whooping-cough, 36 (9) from diphtheria, 36 (6) from diarrhœa and enteritis under 2 years, and 69 (16) from influenza The figures in parentheses are those for London itself, in which, it will be noted, there has again been no death during the week from measles, scarlet fever, or enteric fever

---

Voluntary Hospitals and Poor-law Infirmaries. Mr Reginald E Watson acting chairman of the West London Hospital, has suggested that there should be a conference between the chairmen of the London voluntary hospitals and "those responsible for the future health services of the County of London" to discuss "whether rivalry or coöperation is to be the ruling policy"

Manchester Coroner's Annual Report.—The city coroner, Mr C W W Surridge, states in his annual report that during 1926 the number of cases referred to the coroner totalled 1130 Inquests held numbered 633, a decrease of 40 compared with 1925 The chief cases were deaths due to motor vehicles 87—an increase of 30 on the previous year tram-cars, 4; scalds 121; burns, 18, manslaughter and murder 5, and alcoholism, 10

Home Office. But whether the resolution is regarded as in the interests of the public or in the interests of the profession, it is unlikely to lead to any change of policy. The Home Office and the Director of Public Prosecutions have adequate facilities for summoning whatever expert testimony may be required.

English traditions do not encourage the practice of straining every nerve and employing every possible resource in the endeavour to obtain a verdict of "guilty" at all costs. The duty of the prosecution is not to press for a conviction but to present the facts fairly to the court and jury. The Home Office may show itself reluctant to select a large standing panel of medical and surgical specialists to enter the witness-box on behalf of the Crown whenever similar experts are likely to be called for the defence. In so far as the view of the legal profession is material, it would probably be against change. Prosecuting counsel are content to rely—as in the case of the dispute over the criminal responsibility of Ronald True—upon available official or semi-official witnesses giving their evidence with fairness and restraint. The defending barrister will hardly desire a change if it means that he will lose the advocate's legitimate weapon of pointing out to the jury that both in weight and number his own witnesses are superior to those of the Crown. Viewed, indeed, from the angle of the legal profession, the proceedings at Manchester ran a normal course. Both the magistrates' court and the coroner's court felt reasonably satisfied that there was a prima facie case for investigation at the assizes; at the assizes the defendants were satisfactorily acquitted, the jury evidently accepting the accounts of the occurrence given by the accused themselves, and attaching weight to the other evidence for the defence. The placing of professional men in the dock on charges which are not substantiated is, of course, regrettable; it is by no means clear, however, that the recent trial at the Manchester Assizes would have been avoided by adopting the principle for which the Leigh and District Medical Society contends.

The Legitimacy Act, 1926.

The date of commencement of the new Legitimacy Act was wrongly stated in this column in THE LANCET of Dec. 25th (p. 1341). The Act is not postponed to July 1st but took effect at the beginning of the present year. In one sense the error was less serious because in its broad outlines the new legislation is retrospective, so that legitimation by subsequent marriage has become possible whether the marriage took place before or after the commencement of the Act. But in three other respects the date of the operation of the Act is vital. To begin with, the parents of a legitimated person must furnish the Registrar-General with information with a view to re-registering the birth of the legitimated person by a date which depends upon the date when the Act came into force—i.e., if the marriage takes place after Jan. 1st, 1927, then within three months of the date of marriage, but if the marriage took place before the commencement of the Act, then within six months of such commencement. Secondly, the new right of an illegitimate child and an illegitimate child's mother to succeed to one another's property if the other dies intestate will operate only where death occurs after the commencement of the Act. Finally, the new law contains an express saving that nothing in the Act shall affect the operation or construction of any disposition coming into operation before the commencement of the Act or affect any rights under the intestacy of a person dying before such commencement. For these reasons it is particularly necessary to bear in mind that the date of commencement of the Act was Jan. 1st, 1927, and the misstatement in a previous issue is the more regretted.

TUBERCULIN DISPENSARY BENEVOLENT SOCIETY.—The Tuberculin Dispensary at 32, Fitzroy-street, London, W. 1, will in future be open on Mondays and Thursdays from 2.30 to 5 P.M.

Public Health Services.

A LABORATORY SERVICE FOR LANCASHIRE.

THE Lancashire Insurance Committee have formulated a scheme for assisting insurance practitioners in the scientific treatment of diseases which call for prompt pathological and bacteriological services, and for simplifying the administrative procedure where stock and autogenous vaccines are required. An insured person is entitled, as part of medical benefit under the Insurance Act, to proper and sufficient drugs (including vaccines) requisite for the treatment of his case. This provision does not, however, extend to laboratory diagnostic services. If an autogenous vaccine is to be prepared, then under the old procedure the insurance practitioner selects the source of supply, obtains a collection and transmission outfit, and pays the laboratory authorities. He afterwards sends the receipted bill to the Insurance Committee, together with a pro forma prescription, when the cost is reimbursed to him. The large increase in the use of vaccines, and numerous inquiries received by the Committee from insurance practitioners in Lancashire have emphasised the desirability for a simplification of procedure, and of relieving insurance practitioners of much correspondence, payment of fees, and other clerical work at present unavoidable. Arrangements have accordingly been made with the Wigan Infirmary (Pathological Department), which is in charge of Dr. W. E. Cooke, to supply stock and autogenous vaccines to the order of insurance practitioners, and to report upon any material sent for examination. Insured persons as such are not entitled to laboratory diagnostic facilities, but it is understood that the Wigan Infirmary Board is prepared to furnish free of cost the diagnostic reports required for these persons. Free outfits are being provided for the collection and transmission of material. Should an autogenous vaccine be required, the necessary material is to be sent accompanied by brief details on the form provided, and a pro forma prescription on the usual official form. Where a stock vaccine only is required, all that need be sent to the Wigan Infirmary is a prescription on the official form. Payment will be made direct to the Infirmary Board by the Insurance Committee. It is clearly stated that the scheme does not supersede existing arrangements for the supply of vaccines, but should be regarded as an alternative provision to be used at the option of the insurance practitioner. The scheme came into operation on Jan. 1st. The laboratory is open day and night, and urgent examinations can be made at any time.

In calling attention to this new service the Insurance Committee reminds practitioners in Lancashire that certain pathological and bacteriological services are provided free out of public funds through public health authorities, chiefly in connexion with tuberculosis, venereal diseases, diphtheria, and the typhoid group of fevers. Where practitioners have been notified of these services they should be used and specimens sent to laboratories with which the district local authority has made arrangements, when the fee will be paid direct by the authority to the laboratory.

PORT SANITATION.

THE annual report of the Surgeon-General of the United States Public Health Service refers to the new plan by which emigrants to the States are inspected at European ports. This inspection is regarded as an unqualified success though "a severe drain on the medical personnel of the Service, both on account of the number of officers needed and the special training required." At present 28 regular medical officers of the Service are on duty in Europe in the following countries: England, 4; Ireland, 5; Germany, 8; Scotland, Norway, and Sweden, in each, 2; and 1 each in Poland, France, Holland, Belgium, and Denmark. From the point of view of emigrants and the medical officers of transatlantic liners the new

In conclusion, there can be no doubt that the Mental Deficiency Act of 1913 is not only a sound measure of social reform, but that it is in the highest degree a humane measure I find it simply amazing that any person who has read the Report of the Royal Commission of 1904, or who has any practical knowledge of mental defectives, or who is even really concerned for the welfare of the community, should obstruct a Bill, the sole purpose of which is the remedying of defects which experience has revealed in the original Act I am convinced from the comments and letters which have reached me that workers who have spent years in endeavouring to improve the lot of the unfortunate mental defectives will view the abandonment of the Bill with dismay

I am, Sir, yours faithfully,
A F TREDGOLD, M D.

New Cavendish street, W , Jan 4th, 1927

OSTEOGENESIS IMPERFECTA

To the Editor of THE LANCET

SIR,—I have read with interest the case recorded by Dr Donald Hunter in your issue of Jan 1st There is at present in the Wakefield Hospital a somewhat similar case A J , aged 13, has blue sclerotics His head is large and his eyes are prominent His father and two brothers have also blue sclerotics, but appear otherwise quite normal The first fracture occurred when he was about a year old, and altogether about 23 fractures affecting the lower extremities only A few months ago he was admitted with fractures of both femora and both tibiæ This time his left femur and right tibia were fractured and the right femur snapped after admission without any very obvious cause Pain was severe but of short duration Fractures have been simple except on one occasion when he had a severe compound fracture of the right leg Union has always occurred within the ordinary period The Wassermann reaction is negative

I am, Sir, yours faithfully,
Wakefield Jan 3rd 1927 J W THOMSON.

ADOLESCENT ALBUMINURIA

To the Editor of THE LANCET

SIR,—In reply to Dr Geoffrey Evans's very interesting letter I rather gather, perhaps mistakenly, that he is inclined to believe that the presence of albumin in an after-rest specimen definitely lifts the case out of the class of adolescent albuminuria This is undoubtedly true, of course, in a number of instances, but not, I think, in a good many others; and it is rather the *consistent* appearance of albumin in after-rest specimens that should be regarded, as I suggested in my original article, from a more stringent point of view Thus I find in the last 26 cases before me in which the after-rest specimen contained albumin in otherwise healthy-seeming boys and men, in 16 of them it had disappeared from a subsequent after-rest specimen And I think there is very little doubt that these were all cases of ordinary adolescent albuminuria Even when the after-rest specimen consistently contains albumin it is sometimes difficult, and one would welcome any light on the problem to differentiate it in the absence of any other signs or symptoms from ordinary adolescent albuminuria Thus I have before me the case of a boy of 16 in whom albumin was first found in October, 1925, the after-rest specimen being then free. Examined again, however, on March 4th March 17th, March 31st, May 14th, and August 12th, 1926, every after-rest specimen as well as every after-exercise specimen contained albumin, the boy s general health being apparently excellent and his blood-urea, urine-urea concentration test, and microscopical examination being all normal Had he throughout all these months been suffering from some toxæmic condition or definite damage to renal tissue, it is hard to believe that he would not have exhibited some other manifestations of ill-health And this case, too, I am inclined to think, is really one of harmless adolescent albuminuria The fact remains, however, that in the very great majority of cases the after-rest specimen is free from albumin —I am, Sir, yours faithfully,

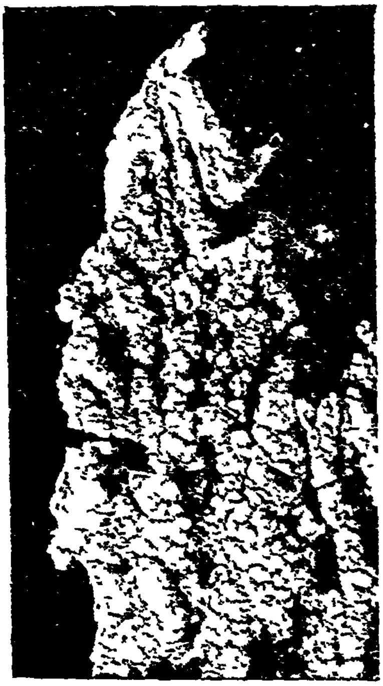
H H. BASHFORD.

Jan 1st, 1927. Medical Department, General Post Office.

DIFFUSE GASTRIC POLYPOSIS

To the Editor of THE LANCET

SIR,—In your recent annotation on a paper by Brunn and Pearl on Diffuse Gastric Polyposis[1] no reference is made to the only case of the kind recorded in England In the *Guy's Hospital Reports* for July, 1926, I described a typical case in which complete gastrectomy was successfully performed by Mr. Lancelot Bromley A man aged 36, had suffered from anæmia since 1917, together with diarrhœa, nausea, and occasional attacks of vomiting. On admission he was found to have complete achlorhydria and constant occult blood in his *stools*, and the X rays showed a well-marked deformity on the greater curvature of his stomach Evacuation occurred with extreme rapidity The hæmoglobin percentage, which had been 65 in May 1925 was now only 44 As it seemed very probable that a growth was present in spite of the long history, Mr Bromley operated on April 18th, 1926 He found that the wall of the stomach was very thick, with the vessels on the outside much injected, it did not, however, feel like a growth As the condition was clearly very abnormal, and was probably the cause of the anæmia it was decided to perform a complete gastrectomy The patient recovered satisfactorily, and when seen ten months later he was looking very well and felt better than he had done since 1917 His hæmoglobin percentage was 85, and no occult blood was present in the *stools*



A portion of the excised stomach photographed after fixation Reduced one-half (Taken from the Guy's Hospital Reports.)

Prof Adrian Stokes reported that the mucous membrane of the excised stomach was greatly thickened and covered with closely packed polypi (a portion of a half scale photograph is here reproduced), which had failed to develop stalks on account of their close proximity to each other Numerous superficial hæmorrhages were present Microscopical examination showed that the condition was one of extreme hypertrophic gastritis There was hyperplasia and hypertrophy of all the coats, most evident in the mucous coat at the cardiac end; there was clear evidence of subacute and chronic inflammatory changes in the mucosa, there was no evidence of tumour formation and no metaplasia of the epithelium

I am, Sir, yours faithfully,
ARTHUR F. HURST

TREATMENT OF TUBERCULOSIS BY MR SPAHLINGER'S METHODS

To the Editor of THE LANCET

SIR,—In his article which appeared in your issue of Jan 1st, Dr Thomas Nelson records the history of ten cases treated by the Spahlinger methods at St George's Hospital in 1913-14 It would be interesting to know why he did not include the eleventh case While admitting into the category of those which he appears to regard as relevant to the issue, two cases one of which received three injections and the other six, he makes no mention of one which may legitimately be described as one of Spahlinger's most striking successes This was that of a man Edward Thomas Allen, now aged 44, whom I had treated at the French Hospital by the Spahlinger methods for some weeks, and whom I handed over to my friend Arthur Latham at St George's because the lay authorities at the French Hospital objected to his continued presence there, on the ground that he did not comply with the French-speaking qualification I have to-day seen and spoken with this man, who is now, and for the last eight years has been, a luggage porter at Claridge's Hotel He reminded me that when I first saw him his weight had fallen from his normal of 13 st 4 lb to 8 st 1 lb · that he was treated at St George's by the Spahlinger remedies for several weeks, receiving an injection on the average of one every two days At the end of that time his improvement was such that he was discharged The improvement has been fully maintained He has completely regained his weight, and is engaged in very active physical work

That this case fails to appear in Dr Nelson's account is susceptible of but two explanations The one is that it was deliberately suppressed by Dr Nelson, which I decline to believe, the other, that the records of the Spahlinger cases at St George's are so defective as to render them completely valueless for any statistical purpose —Your obedient servant

LEONARD WILLIAMS

Harley House, N W 1, Jan 3rd, 1927

THE ABANDONED MENTAL DEFICIENCY BILL

To the Editor of THE LANCET

SIR,—In view of the misunderstanding which appears to prevail in certain quarters regarding the now abandoned Mental Deficiency Bill, perhaps you will be good enough to allow me to attempt to explain the purpose and scope of this measure

It is apparently thought by some persons that the Mental Deficiency Act of 1913, if not actually designed to obtain control of individuals who are quite capable of looking after themselves, has at all events been used for such a purpose, and that consequently any amendment which would facilitate its working should be strenuously resisted There could be no more mistaken view The Act of 1913 was a long overdue measure passed in the interests not only of the community but also of defectives themselves, and it has not inaptly been termed "The Charter of the Feeble-minded" Speaking from a large experience of the working of this Act, I have never known, or heard of, a single instance in which a person has been dealt with under it who was not in need of supervision It should also be pointed out that, contrary to what is often thought, certification under the Act is by no means irrevocable Every first order automatically expires at the end of a year and each case must then be reviewed and, if considered necessary, another order signed A further review takes place at the expiration of another year and subsequently at five-yearly periods

As a matter of fact, far from being applied improperly or too widely, circumstances have combined to interfere very seriously with the working of the Act, and to withhold from thousands of defectives the protection of which they are in need As evidence of this I may state that while the total number of defectives in the country is estimated at approximately 174,000, about half of whom are in *urgent* need of care, the total number dealt with under the Act of Jan 1st, 1926, was only 36,815, of whom 15,733 were under supervision in their own homes

There are two main reasons for this One is the utter inadequacy of existing accommodation, the other is the wording of the definitions of the Act According to the Act of 1913, the mental defect must have existed "from birth or from an early age" Personally, I have always contended, and taught, that the chief purpose of these words was to differentiate between arrested mental development and disorder or decay arising *after* the mind had attained to that degree of development which would enable the individual to transact the ordinary affairs of life, and that the words should be interpreted in this sense But many magistrates, and some medical men, have placed a much narrower construction upon them, they have taken "an early age" to mean the first few years of life, and it is this which has led to considerable difficulty in the administration of the Act

For instance, there are individuals in whom the defect, although undoubtedly of such a nature as to render them in need of care, supervision, and control, has not made itself evident until the years of adolescence The increased demands of life, even of a simple one, have then rendered patent a deficiency which had hitherto been latent There are other cases in which an arrest of mental development has actually been caused during early adolescence, as, for example, by encephalitis lethargica There are yet others where no early history is obtainable It is obvious that cases of this kind, and they are numerous, will be excluded from the protection of the Act by a narrow interpretation of the words "from an early age," and a recent Home Office Committee were so much impressed by this that they recommended that these words should be entirely deleted In my opinion, however, such deletion, in the absence of any definition of mental defect, would have brought within the scope of the Act persons who were not really mentally defective and to whom it was not meant to apply, and I think the Minister of Health was wise in introducing a clause which, whilst doing away with the difficulty resulting from the original definition, yet made it clear that mental defectiveness was not disorder or decay of mind, but "arrested or incomplete" mental development

The question has been raised as to the applicability of the new definition to adults I am very definitely of the opinion that, with the exception of adults in whom the defect has been brought about before the termination of adolescence, the new definition would no more apply to adults than did the old one Since mind reaches a stage of development which may be regarded as normal or adequate for the ordinary purposes of life before the termination of adolescence, it is clear that any change taking place *after* this is not mental arrest Personally, I should certainly object to any definition which extended the scope of the Act to cases of mental disorder or decay, which are already provided for by the Lunacy Act, but I am convinced that it is not intended to do this and that the Bill does not, in fact, do so

It is important to point out that the definition of mental defectiveness in the Bill must be read in conjunction with the definitions contained in the preceding clause For a person to come within the scope of the Act the arrested or incomplete development of mind must be of such a degree as to prevent him from "guarding himself against common physical dangers", or from "managing himself or his affairs", or be so pronounced as to necessitate "care, supervision, and control" for his own protection or for the protection of others peutic aspect, notably in regard to the limitation of the intake of water.

If the authors are correct in regard to the hypercholesterolæmia, the passage which they quote from my paper (or rather from my quotation) ought to be altered to " the frequency of hypercholesterolæmia in *pseudo-uræmic* [instead of uræmic] and chronic *nephrotic* [instead of nephritic] cases "

I am, Sir, yours faithfully,
London, W 1, Jan 1st, 1927 F PARKES WEBER

SYPHILIS AND MALIGNANT DISEASE

To the Editor of THE LANCET

SIR,—I should like to learn of the record of a case of undoubted malignant disease associated with acute generalised syphilis and the effect of the latter upon the former I do not refer to malignant disease following tertiary syphilis or arising upon a syphilitic scar These cases are common and probably due to chronic irritation by an attenuated virus Acute syphilis is destructive to embryonic tissue—e g , the fertilised ovum—hence this query

I am, Sir, yours faithfully,
London, W , Jan 1st, 1927 M W BROWDY.

The Services.

ROYAL NAVAL MEDICAL SERVICE

E C Downer and R H Dummett to be Surg Lts

ROYAL NAVAL VOLUNTEER RESERVE

Prob Surg Lt J A. Kerr is confirmed in rank

ROYAL ARMY MEDICAL CORPS

Capts to be Majs H C Godding, T J L Thompson, and W E K Coles (Prov)

ARMY DENTAL CORPS

Maj J G Worsley retires, receiving a gratuity

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt R S Morshead, from the Active List, to be Capt

ROYAL AIR FORCE

Squadron Leader H B Porteous to be Wing Commander

INDIAN MEDICAL SERVICE.

The King has approved the appointment of Major-General F H G Hutchinson, C I E , as Honorary Surgeon to the King, in succession to Major-General Sir Robert C Macwatt, C I E , who has retired

The King has approved the regrading of the following officers —Capts R W H Miller and C J Smith, Lts T J Davidson, E G Michelson, D MacD Fraser, and S C H Worseldine

Nasiruddin Ahmed to be Temp Lt.

The King has approved the retirement of Maj H R B Gibson

Maj W R Stewart has assumed the appointment of Second-in-Command, Indian Military Hospital, Karachi, vice Capt S D Sondhi, relieved , and Lt -Col D C V Fitzgerald has assumed command of the Indian Military Hospital, Karachi, vice Maj C Newton Davis, relieved. Lt -Col R F. Baird, officiating Inspector-General of Civil Hospitals, United Provinces, on relief, to Allahabad as Civil Surgeon Lt -Col C A Sprawson, professor of medicine, King George's Medical College, Lucknow, and Dr Saivid Ghulam Murtaza, lecturer in medicine, Agra Medical School, have been appointed Members of the Governing Body of the United Provinces State Medical Faculty Maj E A Perry, military medical officer, Roorkee, to be the civil medical officer of Roorkee, in addition to his own duties, vice Capt G A. Hildreth , and Maj -Gen W H Ogilvie, to be officiating Director of Medical Services in India vice Maj -Gen O L. Robinson, granted privilege leave ex-India.

GUY'S HOSPITAL —It is stated that Sir Gilbert Wills, who is a governor of the hospital, has promised to give £50 000 to the bicentenary fund in order that the out-patients' and casualty department may be extended and their equipment brought up to date

Medical News.

SOCIETY OF APOTHECARIES OF LONDON —At recent examinations the following candidates satisfied the examiners in the undermentioned subjects .—

Surgery —F W Barton, Middlesex Hosp , G Danby, Manchester , J H Gillatt, Sheffield , T W Riseley, Cardiff , K Roberts, Liverpool , N S J Roberts (Sect I), Bristol and Royal Free Hosp , and J B Scarr and S Wray Manchester

Medicine —A C F Barrow, Edinburgh , G Danby, Manchester , H J Fordham, St Mary's Hosp , and W E Ivers and C H Spencer, Manchester

Forensic Medicine.—L Ashkenza, Middlesex Hosp , R Bobo, Paris , G Danby, Manchester , S K Rigg, Bristol ; L W Rose, Guy's Hosp , and T. de L Walker, King's College Hosp

Midwifery —F G Hardaker, St Mary's Hosp ; T C Lansdale, Guy's Hosp , and L Wasef, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery F W Barton, H J Fordham, W E Ivers, T W Riseley, J B Scarr, and C H Spencer

UNIVERSITY OF LONDON —At a meeting of the Senate held on Dec 15th the Vice-Chancellor stated that an offer of £10,000 towards the establishment of a Chair of Dietetics had been received from a lady who desired to remain anonymous —It was announced that the William Julius Mickle Fellowship for 1927 had been awarded to Mr Percival Hartley, D Sc , in respect of his work on special problems in connexion with diphtheria and general serology and immunity The Fellowship this year is of the value of about £280 —An offer by Lady Godlee of a sum of money (to be held in trust for University College and University College Hospital Medical School) to found a Rickman Godlee Lectureship in memory of her husband, the late Sir Rickman J Godlee, Bart , was accepted , and it was resolved to convey the thanks of the Senate to Lady Godlee for her gift

University College —A course of three lectures on the Action of the Sense Organs is to be given by Dr E D Adrian, F R S , on Feb 9th, 16th, and 23rd, at 5 P M. ; also a course of three lectures on Biological Action of Light will be given by Dr D T Harris on Jan 20th and 27th and Feb 3rd at 5 P M. , and a course of six lectures on Cytology in Relation to Physiological Processes will also be given by Dr R J Ludford on Jan 20th, 27th, and Feb 3rd, 10th, 17th and 24th at 5 30 P M.

Middlesex Hospital Medical School —A course of four lectures on Current Views on Internal Secretion will be given by Prof Swale Vincent on Jan 14th, 18th, 21st and 25th at 4 P M

Admission to all these courses is free, without ticket

St Thomas's Hospital —A course of three lectures on a subject connected with pharmacology is to be given during February by Prof W Storm van Leeuwen, of the University of Leiden

ROYAL SANITARY INSTITUTE —A sessional meeting will be held on Friday, Jan. 28th, at 7 30 P M , in the small Town Hall, Reading, when a discussion on Cancer will be opened by Sir Stewart Abram, who will speak from the point of view of the physician and the public authority. Dr T Skene Keith will speak on Cancer Research To-day, and Mr J L Joyce on The Present Position of the Treatment of Cancer Prof H R Kenwood will preside On the following day visits will be paid to places in the neighbourhood Those proposing to attend the discussions, luncheon and excursions should notify Dr H J Milligan, Old College Buildings, St Laurence's Churchyard, Reading, not later than Jan 22nd

PEOPLE'S LEAGUE OF HEALTH —The Sims Woodhead series of ten constructive educational health lectures will be given in the lecture room of the Medical Society of London, 11, Chandos-street, Cavendish-square, W , beginning on Monday, Jan. 31st, at 6 P M , and continuing on the following Mondays at the same hour Among those who have promised to lecture are Prof H E Roaf, Mr E B Turner, Mr Vincent Denne, Dr H Gardiner-Hill, Prof B Collingwood, Sir Robert Armstrong-Jones, Dr H Crichton-Miller, Dr L Shore, and Prof M S Pembrey, F R S Tickets and further information may be had from Miss Olga Nethersole, The People's League of Health, 12, Stratford-place, London, W 1

PHARMACEUTICAL SOCIETY —An evening meeting of the Pharmaceutical Society of Great Britain will be held at the Society's house on Tuesday, Jan 11th, at 8 P M., when Mr. J H Franklin will read a paper entitled Notes on Preparations of the British Pharmacopœia, 1914 A discussion will follow. Medical friends of members and student-associates will be cordially welcomed

TUBERCULOSIS OF THE KIDNEY.

To the Editor of THE LANCET.

SIR,—I read with great interest the leading article on renal tuberculosis in your issue of Dec 25th, 1926 Whilst endorsing completely all that is said about the value of early nephrectomy in cases of unilateral infection, I do not agree with those referred to in the last paragraph, who believe that tuberculin "is useless in the management of tuberculous kidney." For several years I have always had my bilateral cases of renal tuberculosis treated by systematic injections of tuberculin in accordance with the usual practice at All Saints' Hospital I do not make extravagant claims for the treatment, as unfortunately there are many cases which do not respond to it, but a large number are materially benefited, as is seen by the increase in weight, the improvement in health, and a general amelioration of the distressing symptoms Several appear cured, and are living their ordinary lives free from symptoms All such, however, are warned to avoid exposure and fatigue and cannot, therefore, be regarded as strictly normal

I am, Sir, yours faithfully,
H L. ATTWATER, M Ch , F R C S

Wimpole street, W , Dec 28th, 1926

IRRADIATION AND CELL DIVISION

To the Editor of THE LANCET.

SIR,—A leading article in your issue of Oct 9th, 1926, referred to recent work by the late Dr T S P Strangeways and others on irradiation and cell division, in which it was shown that cells in certain stages of growth were apparently more easily influenced by radiation than cells which were undergoing mitosis This article drew a reply from Dr J C Mottram, one of the participants in the researches, to the effect that previous work by P Hertwig and by himself had shown the ova of ascaris when undergoing mitosis to be particularly susceptible to radiation I have rather gathered, since Dr Mottram's letter was published, that the inference most people would draw would be that the two positions were mutually irreconcilable, and my object in writing, even so late in the day, is to suggest that this is not so

It would be unfortunate at this stage in the radiological investigations which are being actively pursued at three research laboratories—viz , the Research Hospital, Cambridge, the Radium Institute, London, and the Middlesex Hospital—if their results should even appear to be at variance. Such, however, is not the case, and if any misconception has arisen in the matter it is, I think, to a large extent due to the use of terms not always strictly in the same sense The word mitosis occurs to me in this connexion Two sets of experiments lead to the following conclusions. (1) cells (ova of ascaris) in mitosis are more vulnerable to radiation than when in the resting stage, (2) cells (animal tumour cells) in a state of division suffer no immediate recognisable changes on exposure to large doses of beta radiation, though such doses prevent cells going into mitosis These conclusions may appear difficult to reconcile one with the other, but the difficulty arises partly, I think, from the use of the word mitosis to describe processes which presented themselves very differently to the people who did the experiments Strangeways's observation that cells going through the process of division continue to do so when given doses of X rays large enough to stop cells entering mitosis does not necessarily contradict the observation that cells in mitosis are more easily killed than when these cells are in a resting condition

This letter was written before the news reached me of the death of Dr Strangeways—a terrible loss to radiology A few weeks ago we were discussing the effects of radiation on living tissues, and he said to me, "One is just beginning to see daylight"

I am, Sir, yours faithfully,
SIDNEY RUSS

Cancer Research Laboratories, Middlesex Hospital, W ,

ULTRA-VIOLET RADIATION.

To the Editor of THE LANCET.

SIR,—Dr Weinbren asks for greater detail of the technique adopted for the cases reported by us in your issue of Dec 11th, 1926 Over 200 exposures were made on these seven cases, and the space precluded us from entering into minutiæ as to the reasons for the varying types of lamps used and the varying length of individual exposure The reason why one type of lamp alone was not used throughout is that in our experience better results are obtained in general exposures by using both carbon and mercury vapour—the carbon, as is well known, being richer in the near ultra-violet rays and more penetrating than the mercury vapour, which gives a larger proportion of the far ultra-violet spectrum For local treatment the tungsten arc seems to give better results in irradiating cicatrised areas of any size, whereas the Kromayer, with its quartz applicators of various shapes and sizes, is more useful for smaller areas such as pustules and fistulæ

If Dr Weinbren will again read through our conclusions on Case 3, Hodgkin's disease, he will find that the bogy he has raised is of his own making This case was sent us by a consultant for treatment of the associated secondary anæmia, and our only comment was "The results in this case would suggest that the artificial, no less than the natural, sunlight has a therapeutic value in alleviating the symptoms and retarding the progress of Hodgkin's disease" A long way, surely, from claiming, as Dr Weinbren states we do, that ultra-violet light is a cure, and the only one, for this condition Dr Weinbren then gives his experience of ultra-violet light in two cases of Hodgkin's disease If we understand him correctly, the first patient was suffering from pulmonary tuberculosis, with tubercle bacilli in the sputum, as well as from Hodgkin's disease It is commonly accepted that active pulmonary tuberculosis is a contra-indication to ultra-violet treatment The second case received ultra-violet radiation for one month, stated that he felt better, and there was a decrease in the size of his spleen He then discharged himself from treatment, and after several months returned to hospital in a hopeless condition From this case we should feel diffident in drawing any conclusion

We agree with Dr Weinbren that the value of ultra-violet radiation in Hodgkin's disease remains to be proved

We are, Sir, yours faithfully,
A LISLE PUNCH
RUSSELL WILKINSON.

London, W 1, Dec 28th, 1926

LIPOID NEPHROSIS

To the Editor of THE LANCET.

SIR,—In their very interesting study on the above subject in your issue of Jan 1st Drs Bennett, Davies, and Dodds commence their summary as follows "Apart from albuminuria it is difficult to demonstrate any clinical evidence of renal disorder in the dropsical type of 'nephritis'" Surely the obvious retention of water in these cases must be accepted as evidence of renal disorder, whatever theory may be put forward to explain the occurrence of this retention, when there is no decided complicating cardiac insufficiency Probably the œdema connected with the retention of water, if it comes to involve the central nervous system, plays a chief part in producing one of the gravest complications—namely, so-called "uræmic" convulsions or "uræmic" eclampsia If what was formerly termed "parenchymatous nephritis" is now to be spoken of as "nephrosis," then, obviously, the convulsive attacks (now, owing to improved treatment, less commonly complicating the chronic dropsical cases than they formerly did) ought to be called "nephrotic" convulsions, unless the other foreign term, "pseudo-uræmic" convulsions, be preferred The theoretical explanation of such "nephrotic" convulsions has an important thera-

Births, Marriages, and Deaths.

BIRTHS

ALDRIDGE —On Dec 28th, 1926, at " Ashington," Watford the wife of Dr F J Aldridge, of a son

CLARK.—On Dec 26th 1926 at Bayfield, Kent-road, Southsea, the wife of A Erskine Clark, of a son

ORAM —On Dec 26th, 1926 at Medical Officer's Quarters Wellington Barracks, S W , the wife of Capt A R. Oram, R A.M C , of a son

ORR.—On New Year's Day, the wife of Dr Vivian Bernard Orr Cadogan-gardens, S W , of a son.

MARRIAGES

ANGUS—ANGUS —On Dec 29th 1926 at Northumberland-square Presbyterian Church North Shields William Brodie Gurney Angus O B E M C , M D F R C S E , to Margaret younger daughter of Mr and Mrs. George Angus, of Tynemouth

TUCKER—COLMAN —On Jan 1st, Donald Leslie Tucker, M.R.C S L R.C.P , to Dorothea Colman daughter of the late Canon Colman and Mrs Colman Randolph-crescent, W

DEATHS.

MARTYN-CLARK —On Dec 25th 1926, at Treherbert, South Wales Robert Eric Noel Martyn-Clark, L R.C P. & S Edin aged 39

MURRAY —On Jan 1st Henry George Murray, L R C P Irel , of Carlisle road Hove aged 76

TEACHER —On Jan 1st, at Hollington Fareham, Hants Charles Clarke Teacher, M B C.M , formerly of Edinburgh and Craigend North Berwick aged 74

N B —*A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths*

MIDDLESEX HOSPITAL—Dr A F Voelcker will deliver an Emeritus Lecture in the large lecture theatre of the Medical School on Friday, Jan 11th, at 3 P M The *subject will be the Unscarred Abdomen*

ROYAL SOCIETY OF ARTS—A paper on the Forecasting and Control of Cholera Epidemics in India will be read before the Indian Section of the Royal Society of Arts by Sir Leonard Rogers, F R S, on Friday, Jan 28th, at 4 30 P M The chair will be taken by Sir Michael O'Dwyer, *formerly Lieutenant-Governor of the Punjab* Tickets may be had from the Secretary, Indian Section, Royal Society of Arts, John-street, Adelphi, London, W C 2

RONTGEN SOCIETY—A general meeting will be held in the British Institute of Radiology, 32, Welbeck-street, London, W, on Tuesday, Jan 11th, at 8 15 P M, when a paper on *Some Experiments on the Production of Rapid* Serial Skiagrams from the Screen Image by means of a Cinematograph Camera will be read by Dr Russell J Reynolds At 8 30 P M there will be a special general *meeting to consider the proposed amalgamation with the* British Institute of Radiology

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES—A course of ten lectures on the Philosophy of Social Life will be given by Mr C Delisle Burns, D Lit., at the University of London Club, 21, Gower-street, W C, on Tuesdays, at 6 P M., beginning on Jan 11th—A course of ten lectures on the World of Values will be given by Prof John S Mackenzie, at the Royal Anthropological Institute, 52, Upper Bedford-place, London, W C, on Thursdays, at 5 30 P M, beginning on Jan 13th Full particulars of these courses may be had from the Director of Studies, 88, Kingsway, London, W C 2

LECTURES ON THE CARE OF INFANTS—Under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy a course of post-graduate lectures for health visitors, nurses, midwives, and others interested, will be given at the Infants *Hospital, Vincent-square, Westminster, on Mondays from* 6 30 to 7 30 P M, from Jan 3rd to March 7th The lecturers include Dr J S Fairbairn, Dr Muriel Radford Dr Eric Pritchard, Dr Donald Paterson, Dr W E Robinson, Mr Vincent Denne, Dr H C Cameron, and Mr A H Todd A course of advanced lectures on the same subject, for creche nurses and probationers, will be given by Dr Victoria Bennett, at Carnegie House, 117, Piccadilly, London, W, on Thursdays, from 7 30 to 8 30 P M, from Jan 27th to March 31st Particulars of both courses may be had from the Secretary of the Association, at Carnegie House

MEDICO-LEGAL SOCIETY—This Society has accepted the invitation of the Obstetrical Section of the Royal Society of Medicine to hold a joint meeting at 8 P M on Friday, Jan 21st, at the Hall of the Royal Society of Medicine, 1, Wimpole-street, London, W 1 The subject for debate will be the Ethical, Legal, and Medical Aspects of Abortion, and the speakers will include Dr J S Fairbairn, Lord Riddell, Dr T W Eden, and Sir Travers Humphreys Lord Justice Atkin, the President of the Medico-Legal Society, has consented to take the chair and to sum up the debate at its conclusion Members of the Medico-Legal Society desirous of taking part in the discussion are asked to send in their names to either of the hon secretaries not later than Jan 17th—An ordinary meeting of the society will be held at 11, Chandos-street, Cavendish-square, London, W 1, on Thursday, Jan 27th, at 8 30 P M, when a paper will be read by Dr Halliday Sutherland on a Case Concerning Survival in an Aeroplane Crash A discussion will follow Members may introduce guests on production of a member's *private card*

WELSH NATIONAL MEDICAL SCHOOL—A special meeting of the Court of the University of Wales will be held on Jan 14th to consider the future status and government of this school A draft charter has been prepared by the University Council which provides for its establishment as an independent school in the university, as recommended by a Royal Commission in 1916 At a previous meeting as long ago as October, 1925 (see THE LANCET, 1925, ii, 925), the Court agreed in principle to this scheme, which has, however, been vigorously opposed by the Council of the University College of South Wales and Monmouthshire, to which the Welsh National Medical School has hitherto been attached The chief point of difference appears now to concern the departments of anatomy and physiology The University Council recommend their inclusion in the School of Medicine, but are willing to consider submitting the matter to a *committee of experts*, but the University College of South Wales and Monmouthshire are not prepared to agree to this and have prepared an alternative draft charter providing for their exclusion The University Court, which meets next Friday at Shrewsbury, will decide on Jan. 14th which of these draft charters is to be submitted to the Privy Council *for consideration*

DUBLIN (83) GENERAL HOSPITAL UNIT—The annual dinner of the Dublin (83) General Hospital Unit was held on Jan 1st in the Royal College of Surgeons, under the *presidency of Colonel Sir William Taylor*, organiser of the unit Of the original 30 members, 25 survive, and of these 17 were this year able to attend the dinner The only guests were Colonel A Fullerton, President of the Royal College of Surgeons in Ireland, who was consulting surgeon to the army in the area in which the unit served in France in 1917–18, and Mr A. Miller, Registrar of the College. The chairman spoke with regret of the death of one member, Lieut-Colonel G Jameson Johnston, since the last annual dinner, and of one who had been a guest at several dinners, General R H Sawyer, who had been the deputy director of medical services under whom the unit served

PRIZES FOR INFORMATION ABOUT CANCER—Mr William Lawrence Saunders, of New York, has offered a prize of $50,000 "to any person or group of persons who may discover what human cancer is and how it can positively be *prevented*," and a similar sum "to any person or group of persons who may discover an absolute cure for human cancer" The offer is to stand open for three years and may then be renewed Mr Saunders thinks that "through the lure of a reward this serious problem might be solved through the genius of a lay mind, by chemists, or through unknown *and unorganised medical sources*" *The decision* upon which the awards will be made is to be reached by the American Society for the Control of Cancer and approved by the American Medical Association and the American College of Surgeons

THE LATE DR ALFRED SCOTT—At the age of 71 Dr Alfred Scott died at Crowborough on Dec 22nd Born at Brighton, he was the fourth son of the late Dr S L Scott, who practised in the town, and was educated at Bradfield College He studied medicine at Guy's Hospital and became *M R C S Eng in 1879 and L R C P Lond in 1882* A few years later he settled at Brighton and held a number of appointments in the neighbourhood besides having an extensive private practice He was medical attendant at Brighton College during the whole of his practising life which lasted nearly 40 years He went to live at Crowborough on his retirement four years ago Dr Scott leaves a widow and four children of whom two, Dr Evelyn Scott and Dr P D Scott, are members of the medical profession

Notes, Comments, and Abstracts.

ON THE DANGER OF TREATING INJURIES TO BONES AND JOINTS WITHOUT AN X RAY EXAMINATION

BY W. EDMUND JONES, M.R.C.S. ENG.,
RADIOLOGIST TO THE LEAMINGTON HOSPITAL AND THE STRATFORD-UPON-AVON HOSPITAL

IN the course of radiological practice it is very common to meet cases of injury in which an X ray examination has not been made until long after the accident. The examination is often made only when it is obvious that some unsuspected condition is present; as shown in the radiograph, this may be an unreduced dislocation, a fracture, or a fracture united in poor position. Earlier recognition of the condition would in many cases result in more efficient treatment, and would avoid consequences unpleasant to the medical attendant.

The teaching to-day is that all cases of fracture or suspected fracture, or injury to a joint should be X rayed as soon as possible after the accident. The frequent omission of this important aid to diagnosis has led one of the medical protection societies to issue the following recommendation to its members:—

> "The treatment of fractured bones gives rise to many claims for damages every year, and members are strongly advised to insist as early as possible upon an X ray examination in all cases of injury where a fracture or dislocation has been or may have been sustained. When this is refused or omitted for any reason, a member should provide himself with clear evidence—preferably in writing—to prove that he was not responsible for this neglect or omission."

Treating an injury without knowing its exact nature is like navigating a ship without a compass—a very hazardous undertaking; it means running an unjustifiable risk, and if an unsuspected lesion is found later, or if the end-result is poor, the medical attendant is placed in a very disadvantageous position. I am fully alive to the difference between treating a patient in hospital and in private practice, possibly far removed from all those aids which help so much in the diagnosis and treatment. At the same time the standard of skill expected from the practitioner with no pretentions to special knowledge is getting higher and higher, and in view of the increasing number of cases in which malpraxis is alleged it is of vital importance not to overlook the aid to be obtained from an X ray examination.

Neglect of Radiography.

What are the causes of the continual disregard of this sound principle? The following are some of them: (1) refusal of the patient to consent, usually on the grounds of expense; (2) lack of reasonable facilities; (3) failure of the medical attendant to recognise that a radiograph is likely to be of assistance.

That expense is a real deterrent in some cases is beyond doubt; at the same time the responsibility of deciding against must lie with the patient. The doctor sometimes says that he did not wish to put the patient to the extra expense, but he gets no thanks for this if the end-result is poor. The doctor must make the position perfectly clear to his patient; the use of X rays, if advised, must be insisted upon, and should the patient refuse, for any reason, written evidence of his refusal should be obtained for the protection of the doctor, if he decides to undertake treatment of the case.

There are so many places now which have an X ray apparatus that the excuse that there are no reasonable facilities hardly holds good if the patient is able to be moved. If, however, he cannot be moved, it is usually possible to get a photograph with a portable apparatus; this is of necessity a more expensive proceeding, and in cases of special difficulty the results are not as good as with the more powerful fixed plants.

What are the general conditions which should guide the practitioner in deciding if a case can be moved or not? Patients with fracture of the skull, spine, pelvis, hip, or femur ought not to be moved; but if there is considerable doubt as to the presence of a fracture and the general condition of the patient is good, all these cases may be moved for a diagnostic photograph, except those in which there is injury to the head. Head injuries travel badly, and treatment should rather be based on accurate interpretation of symptoms than on knowledge of the presence or absence of a fracture.

Failure to recognise that a radiograph is likely to be of assistance arises from belief that the injury is trivial or from reliance on clinical signs alone. The following are some of the common fractures shown by radiography in apparently trivial injuries, and frequently overlooked where no X ray examination is made: fractured fingers (especially common in school-boys); fracture of the fifth metatarsal; fracture of the carpal scaphoid, which occurs in 1 per cent. of all wrist injuries; fracture of the base of the metacarpal of the thumb; and impacted Colles's fracture. It is easy to overlook greenstick fractures of many bones, especially of the clavicle in young children. I have had a case diagnosed as sarcoma, which on X ray examination proved to be an overlooked fracture with much callus formation. In sprain or insertion fracture, caused by the sudden contraction of a tendon or muscle tearing away from its insertion a fragment of bone, the fragment cannot always be seen at the time of the injury, though it may be recognised later as a result of the periostitis caused. Examples of this are trigger finger, and the so-called sprained ankle. Compression fractures of the body of a vertebra may also be easily overlooked. Fracture of the pelvis not infrequently results from a fall in the hunting field and in motor accidents, the lesser degree of these fractures easily passing unobserved; generally speaking, however, if they produce no symptoms, little harm is done by the diagnosis not having been made, and this is one of those cases in which an X ray should be taken more for the protection of the doctor than for the good of the patient.

One of the commonest fractures overlooked is intracapsular fracture of the femur, and this is also one which has given rise to much litigation. The signs at the time of the accident are often very slight, the pain is not severe, a thorough examination is not always made, and the condition is treated as a sprain or bruise. In a few weeks, when absorption of the neck has taken place, there is shortening of the limb, lameness and deformity, and the patient wonders how it was possible for the fracture to have been unrecognised. If an X ray examination is now made the fracture and displacement are clearly shown. I have seen such a case in which a very careful clinical examination at the time of the accident failed to show any sign of fracture and no X ray examination was made. Later the patient developed the usual signs and radiography showed the fracture with considerable absorption. In this case it was argued that the doctor had used such skill as could reasonably be expected from a general practitioner, but I am not at all sure that this view would always be upheld.

Fractures near Joints.

To rely on a diagnosis made without an X ray examination is, I consider, most unwise, and it should never be done in any fracture near or involving a joint. This particularly applies to fractures in the region of the elbow joint. I have seen a case, diagnosed as dislocation and thought to have been reduced, where a fracture of the lower end of the humerus was found united in so bad a position that operative interference was necessary. The shoulder is another difficult joint in which to make an accurate diagnosis. What is thought to be a dislocation may prove to be an impacted fracture with dislocation, and in the attempted reduction the impaction may be broken down, leaving the head of the bone in the axilla.

A certain number of fractures are overlooked—in these days of motor accidents, which are a frequent cause of multiple injuries—because the doctor's attention is attracted more particularly to some severe injury, and the less obvious fracture is overlooked. The same thing may happen with unconscious patients. The possibility of a fracture being due to a pathological condition of the bone should always be kept in mind where fracture occurs as a result of slight violence, and an X ray examination in these cases has great value in diagnosis and also in prognosis.

The following injuries are frequently very difficult to demonstrate—a fact which should be borne in mind before putting a patient to inconvenience in travelling, especially as a negative diagnosis is not of much value: fractures of the ribs without displacement, fractures of the sternum without displacement, fractures of the base of the skull, and injuries to joints in infants.

Radiographs help in the treatment of fractures and other injuries by showing the position of the fragments after reduction and later by showing the condition of the ends of the bones and the amount of callus formed. It is, however, essential that the radiographs be interpreted by a competent person; there are many pitfalls for the inexperienced, and to guard against them is the special province of the radiologist. One point is perhaps worth mentioning—an opinion after seeing a film giving one view only should never be expressed upon the position of a fracture.

When should Injuries be Radiographed?

It is usually advised that an X ray examination should be made as soon as possible after the injury. I do not think that this goes far enough. An immediate examination will give an accurate diagnosis, but this is only the starting-point; it defines the practitioner's responsibilities, and leaves no excuse for not applying the appropriate treatment. I suggest that not only should cases be radiographed as soon as possible after injury, but if there is a fracture or dislocation they should be radiographed again after reduction This is the ideal method, but it cannot always be carried out, in some cases, moreover, it is not necessary to have both examinations For example, the great majority of Colles's fractures can be accurately diagnosed without an X ray photograph, so that the diagnostic film could be dispensed with and one after reduction only be taken However certain the diagnosis may seem, however certain it may appear that the dislocation has been properly reduced, and however satisfactory may be the position of a limb after a fracture, it is desirable for the doctor to have a radiograph for his own protection In some cases of special difficulty films may have to be taken repeatedly

During the process of healing, radiological examination may be of considerable assistance All cases which do not appear to be making the expected progress should be radiographed, so that it may be seen how much callus has been formed, it may be deficient or excessive, or there may be non-union Excessive formation of callus is often seen in injuries in the region of the elbow in children, the periosteum is readily stripped off and much callus is formed, sometimes preventing movement of the joint If, after an injury, it is found that a joint has got a limited range of movement, a radiograph should be taken before subjecting the patient to painful manipulations, it is necessary to make quite certain that there is no mechanical cause preventing movement

A common event after an injury to a joint is the occurrence of arthritis, and a note of the presence or absence of this condition immediately after the accident may be of great value should the case later involve litigation

---

SLEEPY SICKNESS IN CHINA.

Dr M O Pfister, of Hong-Kong, formerly acting head of the Department of Neurology at the Peking Union Medical College, has followed up his study of epidemic encephalitis in Europe (*China Medical Journal*, March, 1924) with a résumé of 100 cases which came under his observation while in Peking (Caduceus, August, 1926) He finds the clinical picture of encephalitis in China not essentially different from that in other countries, and the disease not less common there than elsewhere No trustworthy observations are available for the interior of China, but Dr Pfister has reason to believe that the disease has spread all over the country much as it has done in Europe Since 1921 an outbreak has occurred every summer among the foreigners at Peitaiho In Northern China most of the new cases are seen during the dry season from January to March, and 35 per cent. of them belong to the Parkinsonian type In five patients attacks of compulsory fixation of the eyeballs were observed, and Dr Pfister remarks how closely members of the white and yellow races come to resemble each other, and how racial differences vanish from the mask-like face with its loss of expression and its doll-like appearance One difference he does note—namely, the absence of the so-called "ointment" or greasy face in the Chinese patients, owing to the fact that the facial skin of the yellow race is naturally of a somewhat shiny character, while the yellowish tint renders such differences less easily distinguishable than in the white race The first epidemic of encephalitis in China occurred in the spring of 1919, when the disease was at its severest, its course since having become milder. It was probably introduced into China by way of India through the seaports of the southern and eastern coast In Japan, Dr Pfister adds, the disease appeared almost at the same time as in China, and probably along the same lines of transmission

A SUBJECT INDEX FOR THE GENERAL READER

The Subject Index to Periodicals was first issued by the Library Association in 1915 to take the place of Poole's Index, the discontinuance of which had been found to limit the practical utility of public libraries The latest instalment of the Index deals with science and technology (Class-list K) in the year 1922 This instalment comprises 6200 entries obtained from the examination of 300 periodicals, and is adapted for the use of the general reader who wishes to keep in touch with the outstanding publications of the year on a particular subject, rather than for the use of the specialist who requires to know all that has been written, important or unimportant, on his own specialty The Index mentions, for instance, 15 articles dealing broadly with the subject of heredity, with a cross-reference to other headings such as breeding, eugenics, evolution, Karyokinesis, sex, and variation Under cancer there are five items, with a cross-reference to radiotherapy with three items, and a further cross-reference to radium therapeutic use The format is large (9¾ × 12 in.) and the price 1 guinea, the agents for the Library Association being Messrs Grafton and Co, 51, Great Russell-street, London, W C. 1

MENTAL CAPACITY AND DYING DECLARATIONS

In his article last week on cases of suspected poisoning, Dr Roche Lynch remarked that it may become the duty of the medical man to take a dying declaration A correspondent points out in this connexion the doubts which may arise as to the mental capacity of the dying person, but he does not set out his difficulties in detail The giving of evidence as to the mental condition of a patient is often admittedly a matter of considerable difficulty The practitioner in the course of attendance may be satisfied that his patient's own welfare does not demand the help of a consultant, and yet if any situation is likely to arise in which the patient's capacity for managing his affairs or making a will may be questioned, expert advice should certainly be sought In some cases the patient will resent the suggestion that this should be done, and a difficult problem in the conduct of practice arises It is quite true that if any anticipated legal intervention should take place, the expert advice may not be conclusive, for experts are apt to differ about mental capacity and the question of responsibility lends itself to legal argument But the practitioner is acting in the cause of justice and is securing the best position for his patient if he invites him to take a consultant's view as to the circumstances In respect of dying declarations to be used as evidence in a court of law, these are only admitted if they have been made in accordance with the precautions laid down If the responsibility for preparing the dying declaration of a patient should fall upon the medical man, he should not forget that the patient making the declaration has to be (*a*) fully convinced that he is about to die, and (*b*) is in a mental condition to make his statements valid The declaration taken down in the exact words of the dying man should be signed by the practitioner in the presence of one or more witnesses, only something very urgent or peculiar about the circumstances can excuse the witness to his signature The document should be dated, and it might be a point of legal moment that the hour as well as the day should be added

A MESOPOTAMIAN SHEEP.

The diverse requirements of the pathologist are often unintelligible to his colleagues and they are still less clear to the layman Not long ago the medical officer attached to a military unit serving in Irak indented for a sheep which he wanted as a source of fresh blood in his laboratory The animal was duly received and was attached to the equipment, small specimens of blood being from time to time removed from a vein as they were needed After a few months a peremptory communication was received from headquarters at Bagdad stating that no entry could be traced with reference to the return of the sheep's skin after the animal had been used, the skin being required, according to the regulations, for other purposes As both sheep and skin were still being employed in the laboratory a formal reply was sent to the effect that at present the sheep was itself using the skin, and, in the absence of orders to the contrary, it was proposed that for the present it should be permitted to retain it Not long ago, however, a further communication came from headquarters, manifesting renewed anxiety that His Majesty's property should still be unaccounted for on the appropriate returns and asking for further reassurance about its condition. The medical officer accordingly sent the following report: "I have to state that the sheep is still in active life and service Any rumours to the contrary which may have reached Bagdad are without foundation"

THE YOUNGEST MEDICAL STUDENT?

To the Editor of The Lancet

Sir,—In an address to the Child Study Society, which you summarised at the time (The Lancet, 1925, ii, 1101), Mr Macleod Yearsley drew attention to the need for collecting data about *normal* children—their vocabulary and mental development. The following may interest your readers My baby boy is 2 years and 9 months old, this week he was going to the seaside, which he calls "swishy," and watched the packing with great interest and excitement In the midst of it the hotel manager rang up to tell me that he had 20 cases of influenza in the house and urged me not to come To break the disappointment I explained to the baby that we could not go because the people in the hotel had got "bad germs" in their throats, which would get into his He repeated it all after me very slowly and then said, "Paint people's throats with d'iodine so people get better quick, when people better I go 'swishy' Not go now; I doesn't want bad germs in throat"

His medical diagnosis that the people needed their throats painted with iodine is surely remarkable as no mention was made of it by me and it is some time since his own throat was painted Do your readers know of a younger medical student?

I am, Sir, yours faithfully,

Leatherhead Surrey, Jan 1st, 1927. Marie C Stopes

DIET OF CHILDREN UNDER SCHOOL AGE

THE National Association for the Prevention of Infant Mortality has been investigating the diet of children, and after studying the various dietaries given by a large number of Poor-law authorities in this country has drawn up what is to be regarded as the basis of a suitable dietary for children between the ages of 1 and 5 years

The following are essential (1) A minimum of 1 pint of milk daily This should be boiled or pasteurised, unless Certified or Grade A (tuberculin tested) milk is supplied (2) A minimum of 2–4 oz of butter a week A daily dose of cod-liver oil may replace this or permit some reduction (3) A minimum of two eggs a week (4) In the case of young children the juice of orange, tomato, grapes, or lemon (not lime-juice), and for older children an apple, orange, tomato, some green salad or lemon-juice daily (5) Meat or fish—a minimum of 2–4 oz a day, unless an egg is being given (6) Drinking water should be freely available for every child

The amounts of food suggested above are only to be regarded as average quantities, and the needs of individual children must be a matter of observation The following are additional recommendations of the Association Bread should have the maximum amount of crust—"Standard" bread may be given at times Oatmeal may be included in the diet if the daily minimum of a pint of milk is increased Potatoes after being well scrubbed should be cooked and served in their skins Children under 5 should have either milk (see above) or cocoa made with milk, they should not be allowed tea or coffee Margarine may be given as food, but *not* as a substitute for the minimum ration of butter or cod-liver oil The daily dietary should contain a ration of cooked vegetable in season and of hard food requiring the exercise of the jaws The interval between meals should not be less than four hours and not longer than five Nothing but water should be given during the intervals

THE P B L A A

THE report of the Pathological and Bacteriological Laboratory Assistants Association for 1925–26 has lately reached us It records very satisfactory progress Founded in 1912, the Association now has a membership of over 400 including 101 members who have obtained certificates of proficiency in one or other branch of laboratory technique, 171 ordinary members, and 118 junior members The members in Britain are organised in four branches who make their own arrangements for meetings The London division is naturally the largest and most active During the winter under review they held 16 meetings, partly to attend lectures and demonstrations in various laboratories by qualified experts and partly to hold classes in which the senior members give instruction to the juniors in practical work, subsidiary classes for small groups in, e g, glass-blowing, are also arranged The examinations for certificates have been held as usual under an Examining Council consisting of Prof H R Dean, Prof A E Boycott, and Dr J A Murray, with two representatives of the Association We note that at the last examination 17 candidates were successful out of 38, which is evidence that certificates are given only to well-qualified assistants There is no doubt that the Association has done excellent work in raising the standard and status of laboratory assistants and if it continues to give first place amongst its activities to its educational programme it will go on making good progress to the mutual advantage of the assistants and their employers A five day conference will be held in Cambridge in August next Mr H P Hudson has resigned the general secretaryship, and those who desire to know more of the Association or to make use of its employment bureau should communicate with Mr H Gooding, 10 Holbeck-grove, Victoria Park, Manchester, who succeeds him

HEALTH CONDITIONS IN GIBRALTAR

Mr C W J Orr, Colonial Secretary, in his report for 1925, states that the total estimated civil population of Gibraltar at the close of the year was 17,288, of whom 16,127 were fixed residents These figures represent the population between sunset and sunrise, to calculate the daily population it would be necessary to add some 5000 aliens and 1500 British subjects resident in the neighbouring Spanish town of La Linea, who come into Gibraltar daily The number of births during the year was 372, of which 179 were boys and 193 girls The birth-rate per 1000 was 23 00 The births refer to the fixed population only, as under the Aliens Order in Council no alien may give birth in the colony 256 deaths were registered and the crude death-rate was 14 80 per 1000 Infantile mortality was 83 per 1000, which is the lowest since 1913, and deaths from pulmonary tuberculosis 1 7 per 1000 The number of deaths from cancer was 17, a decrease of 10 on the total for 1924 The year was a very satisfactory one as regards general health There was no disease in epidemic form The sanitary work of the colony is carried out by the city council, who have also charge of the roads, lighting, and hygienic measures in dwellings and the provision of water supply The tourist traffic has developed considerably, owing largely to a system of cheap summer fares instituted by the P and O Steamship Company Gibraltar forms an ideal centre for visits to Morocco and the south of Spain, and passengers from London can now tranship here and reach Fez within a few days of leaving England, or can alternatively visit Seville and Granada and other places of interest in Spain during the space of a short fortnight's holiday The general climate of Gibraltar is mild and temperate, though somewhat hot and oppressive during the months of July and August The meteorological record for 1925 shows 69 1° F as the mean maximum temperature, the highest shade temperature being 89° on August 10th and 17th, and the lowest 41° on March 1st, 2nd, and 23rd The rainy season spreads over the period from September to May The annual rainfall is 35 inches, but in 1925 39 21 inches were registered, of which 19 72 inches fell in November

DONATIONS AND BEQUESTS

Sir Adolph Tuck left, among other bequests, £3000 to his son Desmond, in the hope (without creating a trust in the matter) that he would distribute the money amongst charitable institutions and poor but deserving individuals as he may think proper, £1000 to his said son similarly for distribution amongst hospitals, schools and other charities in Jerusalem under the advice of the London Beth Din and the Executive of the Anglo-Jewish Association, £100 to the Jewish Lying-in Charity, Great Alie-street London, E He also left the following charitable legacies to be treated as capital only £500 to King Edward's Hospital Fund, £250 to the London Hospital, £100 each to the Metropolitan Hospital Kingsland-road, N, the Great Northern Hospital, the Middlesex Hospital, the Brompton Hospital for Consumption, the German Hospital Dalston, the Chest Hospital, City-road, N, the City of London Hospital for Diseases of the Chest, Victoria Park, E, the Great Ormond street Hospital for Children, the East London Nursing Home, Queen Alexandra's Fund for Victoria Jubilee Nurses, the Home and Hospital for Jewish Incurables, High road, South Tottenham, N, the Jews' Hospital and Orphan Asylum, the Home for Aged Jews, Wandsworth Common, S W the Jewish Deaf and Dumb Home, Wandsworth Common, the Jewish Institution for the Relief of Indigent Blind, and the Jewish Convalescent Home and Sanatorium for Consumptives, West Brighton —By the will of the late Mr Sidney Ashton, of Kennington Park-road, London, the testator left £500 each (free of duty) to St Thomas's Hospital, King's College Hospital, Guy's Hospital, and Spurgeon's Orphanage, Stockwell —The late Mr Richard Cobden Michell, of Oakfield, Shoot-up-hill, Cricklewood, N W left by will £1000 to the Middlesex Hospital —By will the late Mrs Susan Wilcockson, of Lushington road, Eastbourne, left £1000 each to St Dunstan's Blinded Soldiers' and Sailors' Hostel, and St Bartholomew's Hospital, and £500 each to the Children's Hospital, Great Ormond street, and Dr Barnardo's Homes —Mr Henry Warner Prescott, of Brantyngeshay, Chilworth, Surrey, besides other bequests left on the decease of his sister over £23,000 to charities including £2500 to the East London Hospital for Children and Dispensary for Women, £2000 to the London Homœopathic Hospital, £1500 to the Western General Dispensary, £1000 each to the Royal Surrey County Hospital, Guildford, the Surrey Convalescent Home for Men, Seaford the Children's Convalescent Home for Surrey, and the Victoria Convalescent Home for Surrey Women, Bognor —Mr Frank Bruce Howden, of Red Cliff, Paignton, who left £32,056, after certain personal bequests directed that the residue of his property be divided into 80 parts, of which he left ten parts to Dr Barnardo's Homes, ten parts to Lord Mayor Treloar Cripples Hospital and College ten parts to South Devon and East Cornwall Hospital, Plymouth, for general purposes, five parts to the East Cornwall Hospital, Bodmin, for the perpetual endowment of a cot to be called the "George Bruce Howden Cot" in memory of his late son, five parts to the Royal Cornwall Infirmary, Truro for a like purpose, and four parts to the Paignton and District Hospital —Miss Martha Jane Guest, of Pendleton left £1000 to the Manchester Children's Hospital, Pendleton, for a "Robert Guest" bed and £100 each to St Dunstan's Hostel for the Blind and Dr Barnardo's Homes —Mr Samuel Lord, of Hale, Cheshire, left £1000 to the Manchester Royal Infirmary, £500 to Ancoats Hospital, and £250 to the Boys' and Girls' Refuges and Homes, Manchester, and £1000 for other charitable institutions as his executors may decide —Mrs Dyson, of Highfield, Scotland-road, Nelson, has given £1000 to the endowment fund of Reedyford Hospital in memory of her late husband

A Statistical Investigation
INTO THE
CAUSATION OF PULMONARY EMBOLISM FOLLOWING OPERATION.

BY W. A. LISTER, M.B. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, SOUTH DEVON AND EAST CORNWALL HOSPITAL.

THE study of post-operative embolism from the clinical standpoint has now been active for roughly 30 years, and during the last decade particular attention and interest have centred around the questions of causation and prophylaxis.

HISTORICAL SUMMARY.

In 1902 Keys published 10 cases of embolism following operations on the bladder, and four years later Boise gave a short review of the previous literature, and made a series of suggestions for prophylaxis, some of them rather unusual. Gibson (1909) again reviewed the literature and summarised the opinions of various writers on the subject. He mentioned that elderly patients and those undergoing operations below the diaphragm seemed more liable to embolism than others. A brief analysis of 14 cases occurring at the Middlesex Hospital was given by Hastings (1907). He drew attention to the fact that symptoms of thrombosis in the veins of the leg are usually absent in cases of massive embolism. Only three cases in his series showed naked-eye evidence of sepsis, but the majority had a slight degree of pyrexia for a few days before the embolism took place. Wilson (1912) published an excellent summary of 36 cases of pulmonary and 11 of cerebral embolism that occurred at St. Mary's Hospital, Mayo Clinic, between 1899 and 1911, and also analysed the surgical practice at the clinic during that period. He noted a progressive rise from year to year in the number of cases of embolism, and a concurrent rise in the number of abdominal operations performed during that period. He advised movement as soon as possible after operation as a prophylactic measure. Symonds (1918) expressed the opinion that massive embolism was uncommon in severe septic conditions, and usually followed a very mild phlebitis. He mentioned its prevalence after abdominal operations, and recommended early movement and the disuse of knee-pillows. Two years later Hampton and Wharton (1920) published a paper based on the gynæcological practice of the Johns Hopkins Hospital. They studied thrombosis of the veins of the leg as a separate item, and drew a distinction between pulmonary infarction and embolism. The former term they applied to cases in which smaller emboli had given rise to clinical signs of infarction, such as pain and hæmoptysis, but had not of themselves proved fatal, while the latter was used to indicate cases in which large clots had obstructed the main branches of the pulmonary artery and had rapidly caused death in the majority of instances. They also observed that massive embolism was not usually preceded by clinical evidence of thrombophlebitis, whereas infarction frequently was. Out of the 21 cases of embolism in their series, only three showed evidence of thrombophlebitis before the embolism occurred, and these three cases included the only two survivors. No summary was given of the series of operations in which these cases occurred. Rupp (1921) published 59 cases of embolism in a series of 22,689 operations. He gave details of all the cases of embolism, but did not analyse the operations, and came to no very definite conclusions. Wharton and Pierson (1922) considered that post-operative chest complications are embolic in origin in a large number of cases. They approached the subject mainly from the clinical standpoint, and discussed the methods of diagnosis. Lockhart-Mummery (1921), speaking at a meeting of the Royal Society of Medicine, expressed the opinion that a combination of venous stasis with the liberation of thrombokinase is required to produce thrombosis and embolism. Gordon-Watson (1922) has described the methods he adopts in prophylaxis, which include the institution of breathing exercises as soon as possible after operation.

SUGGESTED PREDISPOSING CAUSES.

The present opinions as to the factors predisposing to massive embolism after operation may be summarised from the report of the B.M.A. meeting at Bradford in 1924 (THE LANCET, 1924). They are:—

1. Stasis in the veins—for which a number of reasons were suggested, such as loss of fluid from purging, vomiting and hæmorrhage, lowering of blood pressure from shock, morphia, or prolonged anæsthesia, and posture during operation.
2. Sepsis—either at the site of operation or extending from it to the veins, giving rise to the thrombus.
3. The liberation of thrombokinase in the wound.
4. Trauma—especially powerful retraction, causing thrombosis in the veins of the abdominal wall, which spreads along them to reach the external iliac or femoral veins.

In a paper read before the Royal Society of Medicine, Lindsay (1925) laid stress on age as an important predisposing cause of embolism. This paper is an attempt to determine which of these several factors are the most important, and whether there may not be some other factor, not as yet considered, which has a bearing on the question.

SCOPE AND METHOD OF PRESENT INVESTIGATION.

The records of the Pathological Institute of the London Hospital were consulted for the years 1909 to 1925 inclusive, and all examples of pulmonary embolism were taken with the following reservations. First, those cases alone were accepted in which the artery obstructed was not smaller than a branch to a lobe. Secondly, all cases of pyæmia were excluded, and also those cases of heart disease in which no other source for the embolus could be found than a thrombus in the right heart. Thirdly, to meet the objection (Glynn, 1924) that many cases considered to be embolic in nature are really cases of primary thrombosis of the pulmonary artery, all cases were excluded in which there had been any doubt as to the embolic or primary thrombotic nature of the clot found in the lungs. Clinically the cases selected would correspond to Hampton and Wharton's cases of "embolism"—cases in which death occurs rapidly after a sudden attack of dyspnœa and cardiac failure, sometimes preceded by an urgent call for the bed-pan. The following numbers were obtained:—

TABLE I.

Cases in which no operation had been performed	154
Cases following operation	195
Cases following fracture	12
	361

These figures should not be taken to indicate that embolism most commonly follows operation, as there are more than twice as many surgical as medical admissions each year to the London Hospital.

The number of complications present in most of the cases without operation made it impossible to classify them satisfactorily. Again, an attempt to determine whether, as has been suggested, the incidence of embolism is on the increase, proved inconclusive, as there were large irregular fluctuations of the annual numbers, and no statistically significant secular trend could be proved to exist. It was, therefore, decided to confine the statistical analysis to an examination of the cases in which the embolism had followed an operation.

Evidently the best way in which such an analysis could be carried out would be to compare all cases of embolism occurring in the London Hospital throughout the period in question with the total surgical practice of the corresponding period. But practically this is an impossible task—first because all cases of embolism will not have come to autopsy, and secondly because the number of cases treated surgically at the hospital is so vast Consequently the analysis must be based on a comparison between samples of the embolism cases on the one hand and the cases of operation on the other

If N be the total number of emboli following operation that occurred at the hospital between 1909 and 1925, and S the total of operations performed during that period, then N/S will be the true incidence rate Now, if *n be a fair sample of N* and s a fair sample of S, then N/S will equal n/s multiplied by a constant depending on the relative values of n/N and s/S, the constant being Ns/nS Again if n and s are subdivided into categories such as age or type of operation, so that n1 + n2 + n3 + = n and s1 + s2 + s3 + . = s, then n1/s1 and n2/s2 will bear a similar relationship to the proportions between the corresponding subdivisions (N1/S1 and S2/N2) of the total numbers, were these available, the relationship being, as before, the constant Ns/nS, so that N1/S1 = n1/s1 × Ns/nS *Hence a comparison between samples* will prove a true index to a similar comparison between total numbers, and this principle forms the basis of the present investigation * The only error to which such a comparison is liable is the computable error of random sampling The essential condition is that n shall be a true sample of N and s of S, and to ensure this is, of course, the chief difficulty

Since the consent or refusal of the relatives to a post-mortem examination is the only form of selection exercised in determining which cases shall come to necropsy, it seems reasonable to assume that the cases of embolism coming to necropsy are a true random sample of all cases in which embolism occurred In making a sample of the operations performed at the hospital to act as a control series, the following method was adopted Four thousand consecutive cases of major operation were taken from the alphabetical records of surgical admissions from 1916 up to the present time, maintaining the same proportion between surgical male, surgical female, and gynæcological cases, for which separate files are kept, as exists between the numbers of admissions in these groups The *distribution was as shown in Table II*

TABLE II

	Total admissions, 1921–25	Controls taken
Surgical males	23,064	2021
Surgical females	17,592	1543
Gynæcological	4,966	436
	45,622	4000

The term "major operation" is indefinite For a variety of reasons the following arbitrary definition was made All cases in which the peritoneum was opened, cases of malignant disease outside the abdomen in which an attempt at cure was made; removal of peripheral benign tumours, cases of osteomyelitis in which the bone was drained, drainage of deep abscesses in axilla and groin and those situated on the trunk, orthopædic operations involving more than a simple closed tenotomy, all set operations on the long bones, nervous system, and vault of skull, skin grafts, operations on the genito-urinary apparatus, including lithotrity, cystodiathermy, and internal urethrotomy, amputations, fractures of the long bone, skull, and pelvis, dislocations of shoulder and hip, operations for piles and fistula The following cases were excluded All operations on the ear, nose, and throat, except those involving a dissection of the glands in the neck, all ophthalmic operations, repair of minor traumata, including amputation of digits, the drainage of peripheral abscesses not specified above, simple dilation and curettage, cystoscopy, urethroscopy, œsophagoscopy, and sigmoidoscopy, simple dilatation for anal fissure, drainage of empyemata, all operations connected with parturition, whether full term or premature, except Cæsarean section

It would appear reasonable that control cases taken in this way should prove a fair sample of all "major operations" performed at the hospital, because the only selection exercised is the sequence in which the cases appear in the files, and this depends merely on the surname of the patient

PRELIMINARY TABULATION

With the series of cases of embolism and the set of control operations thus obtained, a number of tabulations was made It appeared that sex played no part as a predisposing cause, the proportion of emboli to operations in the two sexes being almost the same Pelvic operations carried no uniformly heavy rate of incidence as compared with other operations, and indeed showed very great variation among themselves

While making these tabulations it was noticed that the largest proportions of emboli were found in those conditions which showed a high average age of incidence, and accordingly Table III was drawn up to show the average age and relative incidence of embolism in a series of types of operation which had been followed by a reasonably large number of emboli

TABLE III

Type of operation	Control cases and per cent of total	Emboli and per cent of total	Average age	Proportion as percentage
	%	%		
Appendicitis	761 (32·1)	25 (18·1)	25	3·3
Inguinal and femoral herniæ	328 (13·9)	8 (5·8)	34	2·4
Gynæcological	465 (19·6)	25 (18·1)	41	5·4
Gastric and duodenal ulcers	252 (10·6)	22 (15·9)	44	8·7
Gall bladder	153 (6·5)	13 (9·4)	48	8·5
Pelvic colon and rectum	130 (5·5)	9 (6·5)	48	6·9
Bladder and urethra including prostatectomy	161 (6·8)	27 (19·6)	56	16·8
Umbilical hernia, (adult)	13 (0·5)	6 (4·3)	63	46·0
Halstedt's amputation of breast	105 (4·4)	3 (2·1)	50	3·0
—	2368	138	—	—

It will be noticed that there are 29 more gynæcological cases shown in Table III than were taken as controls This is due to the *fact that occasionally* gynæcological operations, mostly emergencies, are performed by the general surgeons, and so appear in the files of surgical females Twenty-nine such cases appeared in the sample taken from the surgical female records, and in *this investigation* should clearly be added to the figures for gynæcological cases The table seemed to indicate quite definitely that age was an important factor, with the striking exception of Halstedt's operation, which showed a high average age, but a low rate of incidence for embolism At the same time it was noticed that the cases of embolism following operations on the bladder, rectum, and female genitalia were confined almost entirely to those cases in which an incision through the anterior abdominal wall had been used Out of the 25 cases following gynæcological operations 21 had an anterior abdominal incision, and a similar incision had been employed in eight out of the nine rectal cases and in all the 27 cases occurring after operations on the bladder

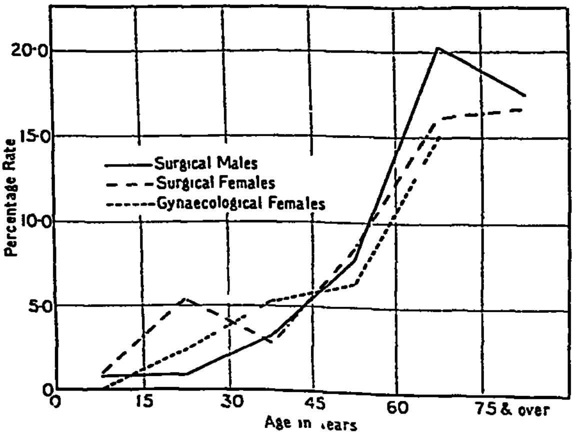
---

* Perhaps the point may be made clearer by an imaginary example Suppose we had to deal with a village in some primitive country inhabited by different races, where there were no organised vital statistics and we wished to know whether these races had different death rates We might arrange to note the nationalities of those who died within a limited period and the nationalities of the inhabitants of every tenth house, taken at random, at a given moment Then if we found that the proportion of the nations among the deaths differed significantly —i e, with regard to the error of sampling—from the proportion among the living, or, what comes to the same thing, that the ratios of deaths to living for the several nations were not all significantly equal, we should justly conclude that the true (and unknown) death rates were also unequal But the conclusion would be quite false if either the selection of the houses was biased, or *the* time for making the enumeration biased—e g, coinciding with a migration to or from the village of a particular nation

Two points, therefore, emerged and seemed worthy of a more critical investigation—namely the effects of age and of an anterior abdominal incision

Age as an Ætiological Factor

Since the age distribution of the gynæcological cases differs slightly from that of the other two groups, it is better to treat the three groups separately In testing the influence of age in the production of embolism one must assume, in the first place, that the age distribution in the control series is a random sample of the age distribution of operations in each of the three sections taken separately throughout the period to which the emboli refer In the second place, it must be accepted that the proportion of emboli in the various age-groups is the same in subjects examined post mortem as in those on whom no necropsy was performed That this is reasonable has already been suggested



The graph here given shows the proportion of embolism cases to sample operations expressed as a percentage plotted against the various age-groups It will be seen that the form of the curves is very similar in all three sections They all rise more steeply after 30 years of age The question as to whether the three sections are comparable, apart from the form of their curves, is immaterial to the point at issue

If it is accepted that the percentage for each age group is subject to sampling error only, then the observed results can be checked by the hypothesis that in the three younger age-groups the number of operations is over-estimated by four times the probable error in a random sample, while the three older age-groups are under-estimated to the same extent This hypothesis is unfavourable to the theory that age increases the liability to embolism, but it is not too widely beyond the probable range of chance fluctuation (The probable error of a frequency is 0·67449 $\sqrt{pqn}$ where p is the proportion of the total n falling in the given class and q = 1 − p)

The curves in the graph were drawn from the figures in the column for the observed rate of incidence shown in Table IV, while the right hand two columns of this table give the results obtained by applying the correction based on the above unfavourable hypothesis In order to keep the total of cases constant in the adjustment, the surplus from the younger age-groups has been distributed over the older age-groups in proportion to the numbers already in these groups The numbers of emboli have not been altered, and are the same in observed and adjusted columns

It is seen that even under the unfavourable hypothesis there is still a marked increase in the incidence of embolism among the older age-groups in all three sections The result, therefore, indicates that age by itself plays an important part in predisposing to embolism and the figures given by Rupp (1921) appear to support this view, as in his series the number of cases of embolism in each age-group rises steadily up to the age of 70 However, as the number of operations in each age-group is not given, his figures are inconclusive on this point

TABLE IV —*Table of Age Incidence of Emboli*

Ages	Emboli	As observed		On unfavourable hypothesis	
		Sample cases and rate per cent		Adjusted cases and rate per cent	
		Surgical Males			
			%		%
0–15	3	399	(0·75)	351	(0·85)
15–30	4	416	(0·96)	368	(1·09)
30–45	13	405	(3·21)	357	(3·64)
45–60	31	392	(7·91)	484	(6·40)
60–75	40	199	(20·10)	246	(16·26)
75–over	4	23	(17·39)	28	(14·29)
		Surgical Females			
0–15	2	205	(0·98)	169	(1·18)
15–30	14	356	(5·33)	312	(4·49)
30–45	12	416	(2·88)	370	(3·24)
45–60	27	319	(8·46)	410	(6·59)
60–75	18	112	(16·07)	144	(12·50)
75–over	2	12	(16·67)	15	(13·33)
		Gynæcological			
0–15	0	1	—	0	—
15–30	2	85	(2·35)	63	(3·17)
30–45	12	232	(5·17)	203	(5·91)
45–60	8	127	(6·30)	172	(4·65)
60–75	3	20	(15·00)	27	(11·11)
75–over	0	0	—	0	—

Note—The observed percentage rates of incidence for the totals in the three groups are very much the same surgical males, 5·18, surgical females, 5·28 gynæcological, 5·38

Influence of the Anterior Abdominal Incision

In order to decide the influence of an anterior abdominal incision (hereafter abbreviated as A A I.) on the incidence of embolism, two provisos must again be accepted The first is that the ratio of necropsies to deaths is not greater in cases with A A I than in other cases, the second, that apart from errors of random sampling, the proportion between cases with and without A A I is the same in the control series as in the whole surgical practice in each of the three sections taken separately throughout the period to which the emboli refer With regard to the latter proviso it should be noted that when deciding what operations should be taken as controls, all cases with A.A.I were included, on the other hand, the remainder of the control cases represent only a fraction of all operations performed at the hospital without A A I In the following tables the cases of embolism following operations not covered by the definition of "major operations" have been excluded, so that the comparison may be placed on a fair basis This correction involved the exclusion of 8 out of 22 cases of embolism which did not follow "major operations"

Table V sets out the data in 15-year age-groups If the two provisos are accepted, and if there were no difference as regards incidence of embolism between operations with and without A A I, one would expect that in any age-group the number of emboli observed would be divided between cases with and without this particular incision in the same ratio as were the operations In columns 5 and 6 are the cases of embolism as observed, while column 7 shows the numbers of emboli following A.A.I's as they would have been expected were there no differences between the incidence of embolism in the two classes of operation

In all three sections and in nearly all age-groups the observed number of emboli in the A.A.I class

TABLE V —*Showing Incidence of Emboli in A A I Cases compared with other Cases of Major Operations*

Ages	Control operations	A A I cases	Other cases	Total emboli	A A I emboli	Other emboli	"Expected" A A I emboli	
							From sample	Adjusted
				Surgical Males				
	1	*2*	*3*	*4*	*5*	*6*	*7*	*8*

45–60	319	188	131	27	24	3	15 9	17 9
60–75	112	75	37	17	15	2	11 4	13 1
75–over	12	12	0	2	2	0	2 0	—
				Gynæcological				
0–15	1	1	0	0	0	0	—	—
15–30	85	70	15	2	2	0	1 6	1 9
30–45	232	182	50	12	12	0	9 4	10 2
45–60	127	82	45	8	7	1	5 2	6 1
60–75	20	13	7	3	3	0	2 0	2 8
75–over	0	0	0	0	0	0	—	—

Note —Col 7 is based on the observed proportions of A A I and other cases among the sample operations Col 8 assumes that the true proportion of A A I operations is greater than the observed proportion by four times the probable error of sampling of the latter

(col 5) is greater than the expected (col 7) The exceptions are all in age-groups in which but few cases occur

The next table (VI) shows that this excess is beyond the range of error probable in a chance distribution

TABLE VI

Surgical Males A A I Group

Ages	Probability* of getting—	A	B
15–30	4 out of 4	0 15	0 23
30–45	11 or more out of 12	0 069	0 11
45–60	25 „ 30	0 012	0 063
60–75	38 „ 40	0 0023	0 015
75–over	4 out of 4	0 18	0 72

Surgical Females A A I Group

Ages	Probability* of getting—	A	B
15–30	13 out of 13	0 0036	0 013
30–45	11 „ 11	0 0019	0 0063
45–60	24 or more out of 27	0 00074	0 0076
60–75	15 „ 17	0 047	0 27

Gynæcological A A I Group

Ages	Probability* of getting—	A	B
15–30	2 out of 2	0 68	0 87
30–45	12 „ 12	0 054	0 16
45–60	7 or more out of 8	0 16	0 39
60–75	3 out of 3	0 27	0 82

* This probability is found by summing those terms of the binomial $(p+q)^n$ in which the index of p is greater than (or equal to) the observed number of embolisms in the A A I class, where p is the chance of an embolism falling in the A A I class (based on the proportion of A A I operations) $q=1-p$ and n is the number of embolisms to be distributed in the given age group

Note —Col A is based on the observed proportions of A A I and other cases among the sample operations Col B assumes that the true proportion of A A I operations is greater than the observed proportion by four times the probable error of sampling of the latter

It will be seen from Table VI that in nearly every age-group with relatively large numbers of cases the result observed is an unlikely one to have been obtained if A A I and other operations were equally liable to embolism The result, however, depends on a random sampling of the operation cases, and is liable to error on this account The proportion of A A I to total operations in each age-group can be adjusted by applying the same method as was used in the study of the age factor—namely, by supposing the proportion of A A I to total operations to be under-estimated by four times the probable error In column 8 of Table V the numbers of emboli expected under this unfavourable hypothesis are given, and it will be seen that even so, on the whole the observed numbers still exceed the expected The evidence, therefore, points to the conclusion that an anterior abdominal incision predisposes strongly to embolism, whatever the ultimate object of the operation An interesting statement in the paper by Wilson (1912) already referred to lends support to this view He shows that in 119 vaginal hysterectomies performed at St Mary's Hospital, Mayo Clinic, between 1899 and 1911, no single case of embolism occurred, whereas in 1712 abdominal hysterectomies 5 cases of embolism occurred, or an average of 1 in 342

Another point of interest, but one less amenable to proof, is that if only operations with an A A I are considered, the incidence of embolism in any given condition depends on the average age of the condition, and is apparently independent of any other factor Table VII , which is Table III modified by the exclusion of control and embolism cases without A A I suggests that this is the case

TABLE VII

Type of operation	Control cases and per cent of total	Emboli and per cent of total	Average age	Proportion as percentage
	%	%		
Appendicitis	761 (37 7)	25 (18 8)	25	3 3
Inguinal and femoral hernia	328 (16 3)	8 (6 0)	34	2 4
Gynæcological	348 (17 3)	24 (18 0)	40	6 9
Gastric and duodenal ulcers	252 (12 5)	22 (16 5)	44	8 7
Gall bladder	153 (7 6)	13 (9 8)	48	8 5
Pelvic colon and rectum	66 (3 3)	8 (6 0)	54	12 0
Bladder and prostate	95 (4 7)	27 (20 3)	55	28 0
Umbilical hernia (adult)	13 (0 6)	6 (4 5)	63	46 0
—	2016	133	—	—

Whether the figures in Table VII are comparable or not depends on two further provisos first, the A A I cases should bear a constant proportion to admissions in each of the classes—surgical male, surgical female, and gynæcological That this is almost the case is shown by Table VIII The number of admissions from among which the control cases were taken and the number of A A I operations in the control series are there tabulated for each class. The correction for the *29* gynæcological cases operated on by the general surgeons, as previously mentioned, has again been made

TABLE VIII

—	Admissions	A A I operations	Proportion as percentage
Surgical males	3860	1198	31 1
Surgical females	2790	858	30 8
Gynæcological	1175	348	29 8

Thus the variation is under 4 per cent , and would not affect the foregoing table to any great extent In the second place it must be accepted that the proportion of post-mortems to deaths following A A I operations is the same in *all three* groups This is *extremely difficult* to verify The officials at the hospital whose duty it is to ask for permission have had many years' experience When consulted, they expressed the opinion that it is in general more difficult to obtain permission from a woman than from a man Consequently the proportion of "gynæcological" permissions granted by husbands may possibly be greater than the "surgical male" permissions granted by wives Hence it may be that the proportion given for gynæcological operations in Table VII is a little too high, and that for operations on the bladder and prostate a little too low The other types of operation would be hardly influenced by this factor

Though not conclusive, the evidence taken as a whole strongly suggests that an operation through the anterior abdominal wall is much more likely to be followed by embolism than is any operation elsewhere, and once an incision is made in this situation the liability to embolism depends on the age of the patient and not on the actual operation performed

RESULTS OF THE INVESTIGATION

The suggested causes of embolism mentioned at the beginning of this paper may now be considered in the light of these observations Lindsay's contention that age is an important factor is strongly supported, though no explanation is forthcoming Trauma to the veins of the abdominal wall by powerful retractors does not seem to cause embolism, as operations in which these are used do not carry an undue rate of incidence If the liberation of thrombokinase predisposed to the condition, then such operations as Halsted's amputation of breast or nephrectomy should show a high rate of incidence, as in these more muscle and cellular tissue is exposed than in any operation through the anterior wall of the abdomen As a matter of fact, Halsted's operation carries a very low rate, considering its high average age, and no single case of embolism following nephrectomy occurs in the post-mortem records examined

As regards sepsis, the experience does not indicate that this exerts any influence in the production of massive embolism A frankly septic condition such as appendicitis does not carry an incidence higher than that suggested by the age at which it occurs and the site of the incision required in its treatment On the other hand, of the six cases in which embolism followed the radical cure of an umbilical hernia in an adult, not one showed any sign of local sepsis at necropsy, yet this condition carries a higher rate of embolism than any other

Stasis in the veins cannot be considered as a whole, but rather with a view to determining which of the many suggested causes for stasis are really significant It is hard to see how posture during operation can exert much influence, at the most it could only partially retard the venous circulation during the operation, and if this partial obstruction can produce thrombosis one would expect thrombosis frequently to follow the use of a tourniquet or intestinal clamp In addition, the present investigation does not indicate any undue incidence following operations in which an unusual posture for the patient is adopted

It is not possible to assess the influence of morphia and the type of anæsthetic Practically every case at the London Hospital is anæsthetised by A C E mixture, followed by open ether, and an appropriate dose of morphia and atropine precedes the induction Conclusions on this point could only be reached by comparison with the experience in other hospitals where a different routine is adopted

It is also hard to determine the effect of shock, purging, vomiting, and hæmorrhage, as these factors vary so greatly in different cases undergoing nominally the same operation

Effects of Muscular Action and Respiration

Now there are two further factors which are generally considered to have a profound influence on venous circulation, but which have received only slight attention in connexion with thrombosis and embolism They are muscular action and respiration

To consider muscular action in the first place, apart from the rest in bed, which is the common lot of all surgical patients, the condition in which movement is reduced to a minimum is fracture of the femur, treated as it is by immobilisation of the limb in addition to recumbency. So far in this article fractures have hardly been mentioned As a matter of fact, fracture of the femur seems very frequently to be followed by embolism, the liability increasing with age as in all other conditions Other fractures, which are either uncommon or involve less complete inertia in their treatment, do not show a similar high incidence In this series the figures for fractured femur show nine cases of embolism with 80 controls, giving a proportion of 11 per cent In operations through the anterior abdominal wall there were 174 cases of embolism and 2404 controls, or 7 2 per cent, while for other operations the proportion was 1 6 per cent (21 emboli and 1315 cases) If it be admitted that these figures are comparable, and the same arguments apply here as in previous comparisons, fracture of the femur must be regarded as carrying a relatively great liability to embolism, and the dangers attending complete muscular inactivity must be recognised

Secondly, as regards respiration It is generally admitted that the commonest source from which massive emboli arise is the great veins of the lower abdomen—namely, the iliac veins and their larger tributaries In the present series, where evidence as to the origin of the embolus was forthcoming, these veins accounted for 97 5 per cent of the cases with an anterior abdominal incision, and 50 per cent. of the remainder Now these veins are not surrounded by muscles, and are therefore deprived of the assistance given by muscular action, and depend almost entirely on respiration for the maintenance of the blood flow through them Respiration performs this function in two ways During inspiration a negative pressure is set up, which draws blood into the thorax, while at the same time the diaphragm descends, raising the intra-abdominal pressure, and by a *vis a tergo* drives the blood from the abdominal into the thoracic veins The venous return from the head and upper limbs depends on the first of these methods, assisted to some extent by gravity, and costal respiration will suffice for its maintenance, but this is not the case in the abdomen, where the venous return depends mainly on diaphragmatic action, and if this action be inhibited, stasis will result

If, then, diaphragmatic respiration plays so important a part in maintaining the circulation in the large abdominal veins, and if, as the tables show, incisions through the anterior abdominal wall so strongly predispose to embolism, it would seem reasonable to suppose that such incisions in some way modify this form of respiration Now the raised intra-abdominal pressure caused by the downward movement of the diaphragm will give rise to pain by stretching an incision in this situation but in no other, and hence in such cases this form of respiration will tend to be reduced to a minimum also Stasis in the iliac veins and their tributaries from this cause would certainly seem to account for the great preponderance of emboli following operations performed through the anterior wall of the abdomen There is one example of an incision in this situation which is little liable to stretching in this manner, partly owing to its position and partly to the firm pressure that can be applied to it by bandages This is the incision used in the radical cure of inguinal and femoral herniæ, and it will be seen from Table VII. that this operation does indeed carry a lower rate of incidence for embolism than would be expected from its average age. How far the prophylactic measures based on these considerations are effective cannot at present be determined, as no large series of cases in which they have been carried out has been published.

It is beyond the scope of this paper to discuss the details of these measures, but it would appear that massage to the lower limbs and breathing exercises should be instituted at the earliest possible moment after any abdominal operation, particularly if the patient is over 40 years of age, and that similar precautions be taken in cases of fracture of the femur. They should, of course, be stopped at once if the slightest suspicion arises that a thrombus has formed In addition, particularly in elderly subjects, if it is possible to perform an equally efficient operation by any other route than by way of the anterior abdominal wall—for instance, some cases of hysterectomy—this route should be adopted

No claim is made that these conclusions are original They have, in particular, been emphasised by Gordon-Watson (1922), who has advocated prophylactic measures in the lines stated above, but so far as the writer's knowledge goes, no *statistical* evidence based on a large series of cases has ever been put forward in their support

SUMMARY.

1 195 cases of pulmonary embolism following operation, and 12 cases following fracture, taken from the records of the Pathological Institute of the London Hospital, are compared with the surgical practice of the hospital, as represented by 4000 major operations taken at random from the surgical records

2 The comparison indicates that there are two outstanding factors which predispose to post-operative embolism—namely, the age of the patient and an incision through the anterior abdominal wall In addition, fracture of the femur carries a high rate of incidence for this complication

3 Free muscular action and well-balanced respiration, both costal and diaphragmatic, are the most important factors in maintaining efficient venous circulation Free muscular action is conspicuous by its absence in the treatment of fracture of the femur, and it is suggested that inhibition of diaphragmatic respiration accounts for the comparatively high incidence of embolism after operations through the anterior abdominal wall

4 Prophylactic measures should be directed towards the restoration of these two functions at the earliest possible moment after operation

In conclusion, my thanks are due to Prof Major Greenwood, of the National Institute for Medical Research, and to Prof H M Turnbull, of the London Hospital—the former for his invaluable assistance in supplying the general outline of the investigation and the statistical examination of the figures, and the latter for other help and his kindness in allowing me to use the records of his department

THE NEW WESTMINSTER OPHTHALMIC HOSPITAL — The new building in Broad-street, W C, which is now being erected, consists of eight floors and a basement The out-patients' department is on the ground floor, the first floor is given up to offices and the research department, on the second are the private wards for paying patients, the operating theatre, and the house-surgeon's quarters The next two floors are respectively for wards for women and children and men, the nurses will live on the fifth floor, and the two uppermost storeys will be used for kitchen and service purposes There will be room for 85 in-patients, the present building at Charing Cross accommodates only 42

ON THE NATURE OF IMMUNITY TO IMPLANTED MALIGNANT TUMOURS

BY THOMAS LUMSDEN, M D ABERD

(From the Department of Experimental Pathology, Lister Institute)

(WITH ILLUSTRATIVE PLATE)

IN communications published in THE LANCET during the last year or two some observations were recorded which it may be well to recapitulate very briefly

Primarily it was the fact[1] that normal and tumour tissues can be cultured for some weeks in vitro, in pure serum alone, which made it possible to test conveniently thereon the effects of various body fluids from normal and from immune animals. Of the tumours used the mouse carcinoma M 63 grows most freely in vitro Jensen's rat sarcoma (J R S) is also easily cultured The rat carcinoma (R 9), Prof Ledingham's guinea-pig sarcoma,* and human breast cancer grow freely only when very vigorous fragments are obtained

The next advance[2] was the observation that if fragments of any of the above tumours were injected into a heterologous animal—e g, rabbit or sheep—the serum of this animal (previously innocuous) became highly toxic to cultures of the antigenic tumour, killing the malignant cells within a few minutes with certain characteristic signs[3]

The toxicity of such a serum was later shown to be not entirely specific, thus an antiserum to human breast cancer (made in a sheep) proved lethal in vitro not only to human but also to mouse cancer cells,[4] while it had not the slightest harmful effect on cultures of normal mouse tissues

Last year an attempt was made to apply these reagents in vivo An antiserum made against J R S was injected into a J R S tumour of the foot of a rat and the circulation in the part was shut off for two to three hours Regression of the tumour then always took place and the rat was thereafter immune to J R S in every part of its body Some months ago[4] it was reported that if a rat had a J R S tumour of each of two feet, the cure of one of the pedal tumours in the above way was invariably followed by reabsorption of the untreated tumour of the other foot Rats so cured were hyperimmunised by many weekly injections of fragments of J R S (H rats), but, somewhat unexpectedly, it was found that J R S cells could be grown freely in vitro in the serum (H S) of such hyperimmune rats, even in the presence of many leucocytes spreading out from a fragment of the spleen of an H rat cultured in the same drop It was, in other words, found impossible at that time to demonstrate the existence of antibodies in the serum of a rat which had been hyperimmunised against sarcoma The problem, "When an animal has been rendered resistant to a particular tumour wherein does its immunity consist?" remained unsolved The experiments described below throw some light on the whole question

Experimental Methods and Results

The methods employed were mostly those detailed in the previous communications One or two other procedures are mentioned below while describing the experimental results obtained

(a) *Study of Immunity to Heterologous Tumours*

When the mouse cancer M 63 is implanted into the flank of several young adult rats, in some of these, as is well known, the mouse tumour cells proliferate freely for a week or so and then regression takes place In several cases such a tumour was removed when the size of a small haricot bean, that is at its maximum growth (seven days), a small portion was fixed for histological examination, another part was cultured in vitro and grew freely for two to three weeks, the remainder was minced and fragments were inoculated into six mice and six rats

---

* For specimens of these tumours I am indebted to Dr J A Murray, F R S, Director of the Imperial Cancer Laboratory, in whose reports descriptions of the growths can be found

[1] THE LANCET 1924, ii, 65

[2] Ibid 1925, i, 383

[3] Ibid, 1925, ii, 539

[4] Ibid, 1926, ii, 112

The fixed portion when cut and stained demonstrated that the tumour cells, which showed many mitoses, were individually like ordinary mouse cancer cells but the plentiful stroma and the general arrangement reminded one of the appearance of rat cancer grown in the rat—e g R 9

Of the six mice inoculated the tumour grew progressively in four In the six rats the fragments were imperceptible after the third day; even the transient proliferation which occurs when M 63 cells from a mouse are injected did not take place The tumour cells instead of becoming acclimatised had in effect been attenuated by their residence in the young adult rat In infant (24-hour) rats whose resistence is very low the opposite appears to be the case, and acclimatisation occurs to some extent

The results obtained by the application of different sera to cultures of M 63 cells which had previously been propagated in the rat or the mouse respectively were instructive Table I shows these results

TABLE I

Serum applied	Effect on culture of M 63 cells grown in a rat	Effect on M 63 cells grown in a mouse
Serum of the rat in which the M 63 was grown.	No damage	Rapid death (5 mins)
Serum of any other rat which has grown an M 63 tumour	"	" "
Serum of a rat in which the M.63 implantation did not grow even temporarily	"	Death in 15 mins
Anti-M 63 (rabbit) serum	Death (10 mins)	Rapid death (5 mins)
Antiserum against J R S from sheep	" "	" "
Antiserum to human mammary cancer (sheep)	Death (30 mins)	" "
Anti-fish-roe serum (rat)	No damage	Death of some cells

It can be shown, then, that the serum of a rat in which an M 63 tumour is growing contains, after seven or eight days, a high titre of antibodies against mouse-grown M 63 cells Four days after inoculation these antibodies begin to appear and the titre remains high for over three months at least. When such a serum is applied to a culture of M 63 from a mouse it rapidly kills all the actively migrating cells It is, however, impossible to demonstrate the existence of these antibodies if the serum is tested on cultures of M 63 fragments taken from a rat

The rat-grown M 63 cells are, in some as yet undefined way, specifically protected against these rat-made antibodies as far as in vitro experiments go That this protection is not merely due to selection of especially resistant cells is suggested by the in vivo results referred to above Its nature will be discussed later

Antisera against J R S or human cancer (made in sheep) or against M 63 (made in a rabbit) kill M 63 cells grown either in the rat or mouse, but even to such sera the rat-grown M 63 cells are slightly more resistant than ordinary M 63 cells from a mouse

(b) *Study of Immunity to Homologous Tumours*

The above observations suggested that possibly, after all the serum of rats hyperimmunised against J R S (H rats) did contain antimalignant bodies, although, as in the case of rat-grown M 63 cells, their presence could not be demonstrated on rat tumour cells The serum of such H. rats was therefore tested on cultures of M 63 (from mice) Serum drawn from an H rat seven or eight days after the last of several weekly reinoculations with J R S invariably damages and when of high titre or if two or three times reapplied kills in vitro cultures of M 63 with all the characteristic appearances seen when death occurs following the application of antisera (Fig I B) When of low titre only certain selected cells are so killed, generally, but not always, these susceptible cells are at the periphery of the culture ("outliers") The effect is very similar to that produced on cultures of M 63 by the serum of a rat which has been inoculated six or eight time with fish roe

This evidence of the existence of antimalignant bodies in H serum and the fact that they had, unaided no deleterious effect on in vitro cultures of J R S led to a further search for some other factor which might render them lethal. since they were unlikely to be produced without some purpose. The most likely adjuvants were the phagocytes These could best be isolated from peritoneal exudate, a fluid in any case worthy of investigation, since it had already been shown that once a rat had been cured of J R S ,[2] fragments of this growth could be inoculated weekly into the peritoneum (or anywhere else) without harm, whereas such an injection into normal rats gave rise to multiple tumours

To investigate these points the following method was used Fragments of J R S, about 0 25 c cm in all (4 to 5 c cm of broth was later found almost as effective and more convenient), were injected into the peritoneum of immune, of normal, and of tumour-bearing rats After four hours the exudates were removed by means of a sterile syringe This is not an easy procedure and often a very small amount of fluid is obtained, sometimes only a few drops If drawn off two hours after injection of broth much more fluid can be got but it is generally too dilute and is ineffective The more concentrated the exudate the better The exudate was centrifuged for a minute or two, the supernatant liquid was run into a capillary tube, and sealed for use later The cells were now washed with 40 or 50 times their bulk of Ringer's solution and again centrifuged, the fluid pipetted off, and the cells with (to avoid dilution) the least possible amount of Ringer were run into a capillary tube, the ends of which were sealed in a flame

The cellular and fluid content of the peritoneal exudates were tested with controls on altogether well over 600 actively growing in vitro cultures of the sarcoma J R S, &c On such cultures (as previously described) the serum of a hyperimmunised rat has not the least harmful effect, but if washed peritoneal cells from the same rat are added, the migrating tumour cells are more or less damaged and clumped, or are killed Such a serum, with peritoneal cells from a normal rat, is distinctly less injurious to the J R S cells Peritoneal cells from an immune rat plus normal rat serum does not appreciably damage the cultures, while peritoneal cells plus serum from a normal rat (except when one inadvertently selects as normal a naturally immune animal), appears to be an excellent culture medium in which the J R S cells grow and migrate vigorously. In the simplest case it was found in some 80 or 90 cultures, using fluids from ten different hyperimmune and ten normal rats, that the whole peritoneal exudate (four hours) from an immunised rat kills or severely damages cultures of J R S cells invariably though, only after six to eight hours (Fig II), while the exudate of a normal rat causes damage (if any) only in proportion to the natural resistance of the animal Normal tissues grow quite freely in peritoneal exudates In all these experiments the fragments of J R S were propagated in normal serum to begin with, and were refed daily test applications being made only 24 to 48 hours after migration, and growth were well established

It will be seen from Table II that the effects of the P E of a rat immunised against M 63 and of a mouse hyperimmunised to the same tumour confirm the results obtained with P E H

TABLE II—*Showing the Condition which Various Cultures may be Expected to Exhibit 24 Hours after the Application of Different Reagents*

P L N	A	—	—				

In describing the characteristic results obtained the following abbreviations are made use of P, peritoneal, C cells, L, the clear supernatant liquid after the first centrifuging E, the whole exudate before spinning H rat hyperimmunised to J R S N normal rat J rat bearing a J R S tumour, S, serum Thus P C H + H S = the washed peritoneal cells from a rat hyperimmunised against J R S, used along with the serum from the same or another "H" rat D = dead I = inactive—i e damaged A = active migration of cells M 63R = rat immunised to M 63 M 63M = mouse hyperimmunised to M 63

Table III shows in detail the effects of various applications upon J R S cultures The figures represent all the results up to Dec 15th 1926 and include some early and tentative observations, made before the importance of anaerobiosis was appreciated As mentioned later, the experiments were always weighted against the anticipated result and often heavily so It is however, thought that no selection should be made and that the general tenour and the interlocking of the evidence is sufficiently convincing, especially in view of the number of variable elements concerned [5] As was to be expected with increasing knowledge and improving technique, yet more consistent results are now being obtained.

TABLE III

D * = Cells all dead I † = Many dead, some active
A ‡ = Most or all active

Of the observations given in Table III, the following may be regarded as crucial H S, N S, J S, are entirely innocuous to cultured sarcoma cells P E H and P L H are exceedingly toxic, P E N and P L N are less so P C H + H S causes, as a rule, marked damage, P C H + N S does not P C N + H S causes some damage, P C N + N S causes little, if any

If a culture is fixed and stained with iron hæmatoxylin 24 hours after P E H has been applied to it, complete chromatolysis is seen to have taken place The nuclei are pyknotic and later do not stain at all, the cell membrane has disappeared completely and the whole cell is disorganised, becoming a structureless mass of fatty and protoplasmic granules (Fig I c), the changes are somewhat different from those seen when a heterologous anti-M 63 serum is applied to M 63 cells in vitro, or when any other heterologous antimalignant serum is used to kill cultures of the tumour employed to produce the anti serum The chief difference is that in the latter case the appearance of a cell membrane is maintained, though it is clear from the distension of the cell that its permeability to electrolytes has been profoundly altered (Fig I B)

By examination of films of many peritoneal exudates and by testing their effect on cultures, it appears that the sequence of events is as follows Very early (half hour) after the peritoneal injection lymphocytes have made their way out of the blood-vessels they are soon followed by an ever-increasing horde of polymorphs, which at two hours greatly exceed them in number, by four hours the exuded cells are very numerous, polymorphs comprising about 75 per cent, mononuclears 20 per cent, and lymphocytes about 5 per cent of the cells present Coincidently with this migration into the peritoneum, reabsorption of watery fluid is continuously occurring, so that the exudate becomes more and more concentrated and its volume diminishes By this means a titre of the antibody higher than that in the blood is conceivably attained In favour of this view are the facts that P E from a rabbit immunised against mouse cancer kills cultures of M 63 practically instantaneously—i.e, even more rapidly than the rabbit's serum does—and that adding H S to P E H drawn at five hours, only lessens its activity by lowering its titre Dilution is not, however, the only effect which H S has in this way, for if before adding it to P E H or P L H the H S is heated to 56° for 45 minutes, definitely less inactivation takes place

It will be found that there is considerable variability in the effect of P C H + H S on cultures of J R S Sometimes the latter are completely killed, sometimes comparatively slight damage is done For reasons referred to above, the conditions are apt to vary in different experiments in ways not easy to control Even so, the reaction occurs so often as to become convincing when frequently repeated (Out of 92 experiments, in 29 every sarcoma cell was killed, in 39 there was serious, and in only 24 slight, if any, damage) In any case strong confirmation of the existence of a special leucocytic cytase is forthcoming in another direction

If P L H of proved toxicity is heated to 56° for 45 minutes, it becomes quite innocuous to J R S cells, and H S or N S has not the slightest reactivating effect upon it, but if P C H twice washed in Ringer's solution are thereafter kept at 37° for four hours or so in a very small quantity of the Ringer, in a rubber stoppered tube filled with nitrogen, then, adding to the heated P L H either some of these P C H, or even a drop of the supernatant fluid, completely restores its toxicity (Fig III)

Since this is so, and since the P L H drawn at, say, six hours after inoculation of broth, kills sarcoma cells in vitro, while H serum does not, it appears that the leucocytes secrete into the P.L some essential cytotoxic factor Why did they not secrete this factor while still in the blood-vessels [3] One possibility was that the change from aerobic to almost anaerobic life might be one, at least of the determining factors To test this 5 c cm of broth was injected into the peritoneum of an H rat The P E H was drawn two hours later a period at which it is easily obtained in considerable quantity (2–3 c cm) and is dilute and not yet highly toxic to *J R S cells in vitro* A *little of the P E H*, as drawn, was run into a capillary tube and was applied to a culture of J R S About 1 c cm of it was then delivered from the syringe into a centrifuge tube A under a layer of liquid paraffin about 2 cm deep A similar quantity was run into a tube B, which was simply stoppered with sterile cotton-wool Similar steps were taken with the fluid from a normal rat, tubes C and D respectively The four centrifuge tubes were placed in an incubator at 37° C for four hours At the end of this time they were centrifuged and some of the clear supernatant fluid was run into capillary tubes It was conceived that if the leucocytes only secreted their toxic factor when under mildly anaerobic conditions, then the fluid from A, when applied to a J R S culture along with H S, should damage or kill it, while the fluid from B should do so to a less extent or not at all The results of this particular experiment were as follows —

---

[5] The following are some of the more evident variables which have to be taken into account and which make personal observation of the results much more informative than mere tabulation of them 1 Varying titre of antimalignant bodies in the serum or exudate of different H rats 2 Degree of natural resistance in different normal and tumour bearing rats 3 Varying quantity and concentration of peritoneal exudate obtainable from different rats even at the same period after inoculation of broth 4 Varying activity and viability of different cultures of J R S, only experience makes it possible to gauge these accurately Many controls should always be used 5 Degree of anaerobiosis attained while keeping fluids and suspensions outside the body 6 The presence of fat or debris in any exudate has per se a deleterious effect on J R S cultures 7 Red blood corpuscles if present in large numbers, delay or lessen the toxic effects of P E H, &c

J R S culture—
+ P E H (two hours) survived, though slightly damaged
+ fluid A (anaerobic) + H S = all cells killed typically
+ fluid B (aerobic) + H S = active healthy growth of the J R S cells
+ C + H S = a few cells killed others survived.
+ D + H S = active healthy growth (See Fig IV)

The observation confirms the view that the leucocytes only secrete their toxic factor at a low oxygen tension, and this may well be the *condition* which determines their doing so A device which would automatically evoke the toxic factor just when it is required—i e, when the leucocytes have extravasated It is true that in this experiment the pH of the fluid under paraffin in tube A *does not* alter much, when tested it was 7 6, while the fluid in tube B rises to 7 9, but this alteration is probably not the determining factor, since the leucocytes do not secrete their toxic factor in the blood where the pH remains constant *The contents of the tube* C + H S caused some damage, so that even leucocytes from a normal animal have some power to secrete the *cytotoxic factor*, though they do so much less effectively than P C H This confirmed many previous observations on this *point*

Although this leucocytic factor is only manufactured under more or less anaerobic *conditions, once made* it is not particularly sensitive to oxygen, for P L H kills J R S cells in vitro even after exposure to the air

These results all correspond with the fact that if J R S fragments are inoculated into the peritoneum of a normal rat they give rise to progressively growing tumours, while in the abdomen of an H rat they are rapidly got rid of and no tumour supervenes Since they seemed, however, more or less at variance with the observation previously reported,[4] that a fragment of the spleen from an H rat can be cultured in H S alongside a fragment of J R S, the numerous phagocytes and lymphocytes from the spleen intermingling with the J R S cells without apparent harm to either, the experiment was repeated These experiments confirmed exactly the earlier observations, and similar results are obtained if J R S and lymph gland, testis, or thymus are cultured together We must therefore suppose that there is some essential difference between the conditions of the two varieties of phagocytes—viz, those from the spleen culture and those from the peritoneum. Such a variation is the more readily conceivable, since it is found that quite as marked a difference exists in the effects of P E H itself if drawn from the abdomen at varying periods after the inoculation which evoked it Thus P E H drawn less than two hours after inoculation of broth into an H rat's peritoneum is dilute and has little, if any, deleterious effect on J R S cultures, while the exudate taken at four or five hours damages or *kills* such a *culture invariably* One experiment indicated that P E H. drawn at 24 hours has again lost some of its lethal effects

In all cases when two cultures differed in activity the fluid supposed to be the more toxic was applied to the more vigorous of the two—that is, the experiment was weighted against the anticipated result (*Table IV*)

TABLE IV

Slide		Condition before	Application	Condition after
1842	A	+ + + +	P E H	0 = dead
	B	+	P E N	+ + + = active
2042	A	+ + +	Anaerobic P L H + H S	0 = dead
	B	+	Aerobic P L H + H S	+ + + = active

+ Signifies active growth

Special Precautions Required in Experiments

It may be well to summarise some of the special precautions required in the foregoing experiments —

1 All cultures should be grown initially in normal serum and only those in which active migration of tumour cells is occurring should be used for experiments Cultures from two to three days old are generally the most suitable for experimental purposes

2 Draw P E H (with the least possible injury to abdominal organs or fat) four to six hours after the injection which evoked it and apply it before it coagulates, if much exudate is present its toxicity is apt to be low

3 Obtain H S and P E H just before use from a rat seven to eight days after the last of several reinoculations of J R S Test the potency of the H S on a culture of M 63 cells from a mouse

4 To obtain effective P C H draw the exudate two to three hours after broth injection centrifuge and wash with Ringer's fluid, centrifuge again, and remove the supernatant liquid till only a drop or so is left, just enough to suspend the cells Blow out thoroughly the air in the tube containing these with nitrogen and *rubber stopper at once* After four hours in an incubator at 37° C the cells and the liquid suspending them contain the toxic leucocytic factor

5 Avoid dilution of fluids and suspensions; *concentration is very important*

6 If a fluid is likely to be of low titre do not test it on a culture growing from a *large fragment of* J R S, else so much absorption of antibodies may take place that little toxic effect may be demonstrated

7 Use all fluids as soon as possible after they have been prepared, since some of the factors are distinctly labile

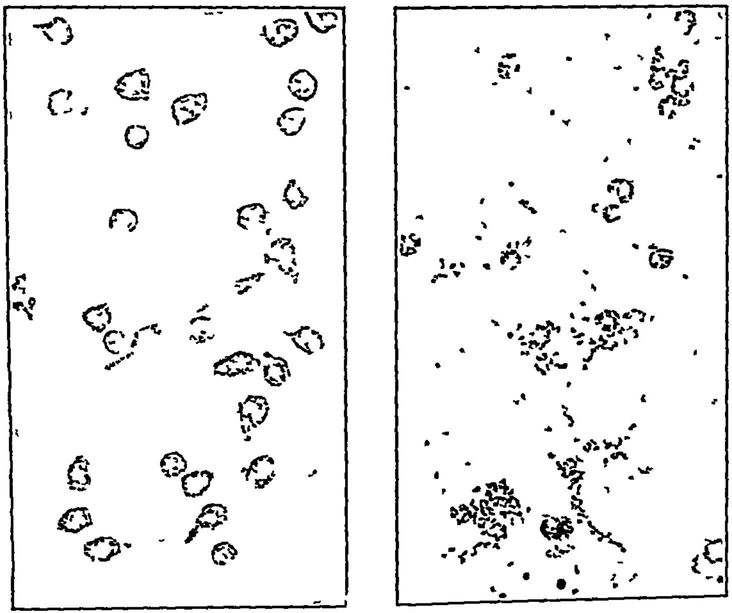
When such precautions as the above are taken inexplicable and contradictory results do not occur Thus when testing the difference of toxicity between P L H kept after centrifuging aerobically and anaerobically respectively If the P E H as obtained was too dilute neither may kill If it was too concentrated both may kill, but if only one proves lethal it is always the anaerobic P L H, and if only minor degrees of damage are forthcoming they always show that the anaerobic is more toxic than the aerobic P L H

In Vitro Tests with Human Breast Cancer.—Only really active encephaloid carcinoma can be grown freely in serum, but from many good vigorous cultures obtained and tested at various times during the past year it is now possible to state that spontaneous human carcinoma reacts in vitro to antibodies similarly to the transplantable tumours of rats and mice Just as antihuman cancer sera kill M 63 and J R S cells in vitro, so do anti-M 63 and anti-J R S sera kill human carcinoma cells, while the serum of H rats is, if anything more lethal in vitro to human than it is to mouse cancer cells, a strong confirmation of the presence of true antimalignant cell bodies in H S (Fig V), for human cancer grows vigorously in normal rat serum

The hope is thus strengthened that if we could cure the transplantable tumours of mice there should be no insuperable difficulty in dealing with the spontaneous tumours of man

Treatment of J R S in Living Rats—The only advance in this direction has been achieved by injecting into J R S tumours the whole blood directly it is drawn from an immunised heterologous animal instead of its serum This manœuvre has the advantage that the injected blood immediately coagulates in and around the tumour and the serum, with its contained antibodies, is localised and gradually expressed by the contracting clot By this means tumours of the feet and also the flank of moderate size (up to a hazel nut or so) can be made to regress sometimes even without constriction of the part Repeated daily injections are generally required in the case of flank tumours, a single inoculation usually suffices for pedal growths Subcutaneous mass ligature close to the tumour of its main axillary and inguinal blood-supply (which has, per se, some curative effect) renders injections of whole antiblood a practically certain cure for a flank growth of moderate size The regression of such a tumour is always followed by absorption of a coexisting tumour of the foot, but the converse does not hold, a flank sarcoma generally continues to grow even after the disappearance of a foot tumour The results obtained in the few attempts made to cure M 63 in living mice by injecting antihuman cancer blood from a sheep into the tumour were much less satisfactory, only two flank tumours regressed out of 30 treated

FRESH PREPARATIONS OF MOUSE CANCER × 200



A

FIG III —Culture of mouse cancer (M 63) originally propagated in normal mouse serum now growing actively in equal parts of serum and of the liquid from the peritoneal exudate (heated) of an immune mouse

B

A similar culture killed by application of heated peritoneal liquid plus a suspension of peritoneal cells from the same immune mouse

The peritoneal cells have reactivated the heated peritoneal liquid, the fresh serum has not

In view of the results obtained in vitro with peritoneal exudates, it is proposed to try whether they will prove curative in vivo They have the advantage of coagulating and also, if drawn after some hours, of containing a high titre of antibodies From the observations recorded above they should be more effective than either serum or blood It may also be possible by means of P E so to damage J R S cells anaerobically outside the body or in the peritoneum of a hyperimmune rat that they may, when inoculated, set up active immunity such as cure of a foot tumour evokes

Discussion

It would obviously be disadvantageous that animals should make antibodies lethal to any of their own tissues, on the other hand, it is well known that they do so to any foreign proteid injected into them How do tumours rank? They pertain to the host in some ways, in others they are foreign to it Their cells live for themselves alone, yet they could not exist but for the stroma which their host provides It is of primal importance to know whether homologous tumours are foreign enough to evoke antibodies in the animals they infest. Animals not infrequently recover from tumours implanted into them How do they manage this? The answer to these questions may best be sought by studying the mechanism of spontaneous recovery Take first an instance where regression always occurs—for example, where a mouse tumour (M 63) is implanted in a rat Here we have the fortunate opportunity of testing in vitro the host's humours on the malignant cells, not only as the latter are originally and in essence, but also when attuned to an unnatural host

It has been shown that M 63 cells removed after seven days' sojourn in a rat live for two to three weeks if cultured in vitro in the same rat's serum, while if left in the rat they would all be dead within three or four days It is clear, then, that in the latter case they do not simply die of inanition (atreptic immunity), but are actively destroyed by some mechanism in the living rat The rat's serum alone is not capable of causing this destruction, for while it kills mouse-grown M 63 cells in vitro, it is quite innocuous to rat-grown M 63 cells It is improbable that simple selection can explain the resistance which these rat-grown M 63 cells show to the rat anti-M 63 bodies, because, if so, we should expect these M 63 cells grown in a rat to be able to survive longer if transferred to a fresh adult rat than unselected M 63 cells from a mouse The reverse is the case As stated above, fresh mouse-grown M 63 cells frequently survive in such a rat and multiply for seven to ten days, while M 63 cells removed from a rat and implanted into another rat die out without any initial period of proliferation Further, if selection were the determining factor it should be possible, by taking the serum of an M 63 rat after it has had time to attain a high titre of antibodies, to kill at least some of the M 63 cells migrating out of a culture of M 63 removed from a rat, say, four days after implantation—i e, before selection had time to act fully This was tested many times, and it was never found possible to destroy in vitro a single M 63 rat-grown cell by applying an anti-M 63 rat serum, although proved to be of very high titre by the rapid way in which it destroyed M 63 cells from the mouse The facts may be interpreted by supposing that by some special means every tumour cell that grows in any animal is specifically protected against antibodies and complement existing in its host's blood serum

The experimental results are consistent with the view that this specific protection is largely a function of the cell membrane

The tests reported above demonstrate two essential facts · (1) Mouse tumour cells growing in a rat evoke specific antibodies in their host, and (2) these tumour cells tend to acquire some protection, some means of resisting the lethal effects of such antibodies.

The evidence for the first of these conclusions is plain and easily demonstrable since we can get rid of the second and confusing element by using M 63 cells not rat- but mouse-grown and so unprotected

These facts suggest the important possibility that animals may even be made to produce antibodies to tumours of their own species (homologous tumours) The observation that H S kills M 63 and human cancer cells shows that it does contain antimalignant bodies It is improbable that these would be produced without some purpose, yet they are not, acting alone lethal to J R S cells Is there a second factor which renders them so ? The evidence points clearly to some secretion or excretion of the extravasated leucocytes when under more or less anaerobic conditions as such an adjuvant factor H S alone does not injure cultures of J R S , H S. + washed P C H does Observation of the cultures shows that the influence of the leucocytes is not phagocytic, death of the J R S cells occurs if the leucocytes are in the same drop of serum, even without actual contact Further, P L H alone kills if drawn after the leucocytes have been given time to excrete their toxic factor into the peritoneal cavity. The conclusion seems justified that the second factor, which, added to that present in the serum of an immune animal causes the death of homologous tumour cells is something exuded by the leucocytes The action is a gradual one, taking several hours to cause death, a delay which is absent in the case of heterologous tissues which are killed almost instantly by the lysins they evoke Thus H S takes six to eight hours to kill J R S cells in vitro, even when adequately supplemented by leucocytic secretion death occurring only after gradual disappearance of the cell membrane while anti-M 63 serum from a rat kills mouse-grown M 63 cells in five minutes or less , in this case the cell membrane remains, but its permeability is profoundly altered The presence in the latter serum of antimouse bodies, as well as antimalignant bodies, and the absence of antirat bodies in H S seems to be the fact which determines this difference Heterologous antispecies bodies can be complemented by the pre-existing complement of normal serum Autogenous antibodies only kill in conjunction with the much less rapidly destructive specific substance produced by extravasated leucocytes It is probable that the leucocytes under the aerobic conditions in the blood-vessels produce a complement lethal to heterologous tissues It appears certain that they only excrete the specific cytase potent against autogenous tissues when they are under comparatively anaerobic conditions

Fresh Preparations of Human Breast Cancer × 300

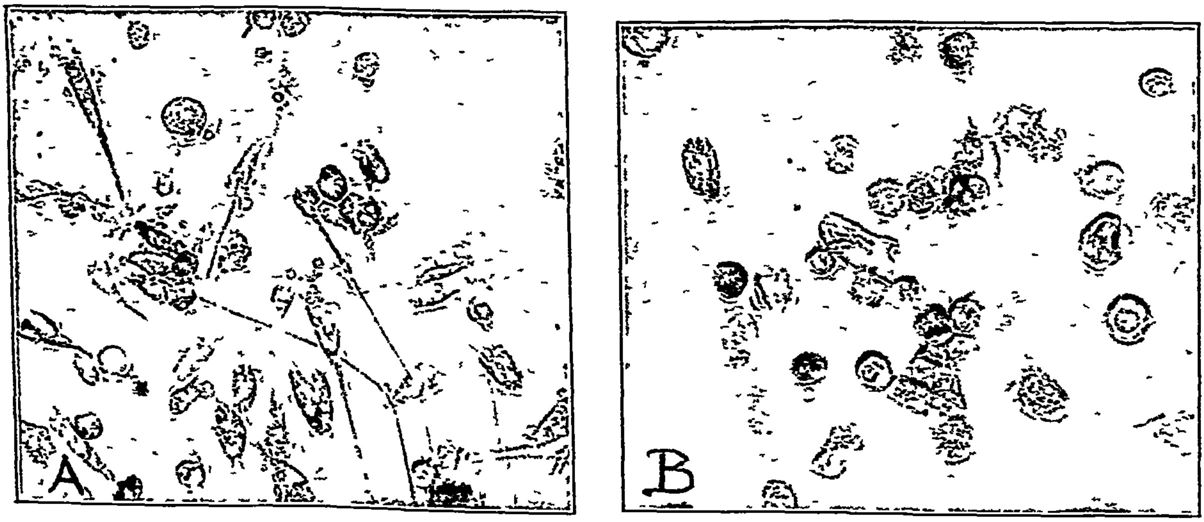


Fig V—A vigorous culture of human breast cancer growing in normal rat serum.

The same field one hour after three applications of the serum of a rat immunised against Jensen's rat sarcoma. All cells dead.

There is some reason to think (two rats whose P L N. was toxic to J R S cells were, when tested later, found to be naturally immune) that by the two factors referred to above natural tumour immunity is managed The humoral factors alone are insufficient, the second leucocytic factor may here also be required. Whether this is applicable to natural immunity as a whole is at present unknown, but the point should be easy to settle

Specificity—It is well known that while recovery from the rat cancer (R 9) protects a rat completely from reinoculations of that tumour, it does not convey adequate protection against J.R S In part this may be a question of titre, since J R S is the more virulent of the two tumours, thus, of six rats hyperimmunised to J R S , all were found completely resistant to R 9, but there is little doubt that there is more in it than this There appears to be a definite degree of specificity in the immunity to any particular tumour The antibodies in H S can be shown to be more or less effective against many varieties of malignant cells, and the natural complement of the blood is also non-specific There remains the special cytase excreted by extravasated leucocytes Here definite specificity can be demonstrated, for while the peritoneal exudate of a rat hyperimmunised to J.R S. tumour drawn after four hours kills J R S cells invariably, it does not kill cultures of M 63 either from the mouse or from the rat Similarly, though the P.E of a rat immunised against M 63 kills rat-grown M 63 cells it does not kill J.R S cultures

It seems then, as hinted above (P C H + H is more toxic than P C N + H), that when an animal has been educated to produce leucocytes which excrete this special cytase it retains a specific facility for repeating the process

When we consider that all these lethal effects were produced in vitro by a single application, we must appreciate how complete the immunised animal's protection must be, for the J.R S cells implanted in it are subjected to a continuous and intensive bombardment by amboceptor and cytase constantly refreshed and progressively concentrated

What, then, are the various results which may follow the implantation of homologous tumour cells into any animal—e g , of J.R S cells into a rat—and how are these results determined ? The possible results are these : (1) The tumour cells may be destroyed and become imperceptible within the first two or three days. (2) They may grow progressively and cause the death of the animal. (3) After a preliminary period of proliferation, natural recovery may take place The experiments above recorded suggest that these results may be determined as follows In all cases the implanted tumour cells become surrounded by fluids and white blood corpuscles from the host's blood and lymph vessels

1 If the rat is naturally resistant or has been immunised, the exuded serum *contains antimalignant* bodies and the leucocytes secrete a specific cytase Together these destroy the J R S cells, and the resultant debris is removed by the phagocytes

2 If the animal is susceptible, the implanted *tumour cells meet with fluids and* cells relatively innocuous to them (cf peritoneal exudate of a normal rat) they survive, and the reaction they induce in the host's tissues results in the production of a stroma and blood-supply which allows progressive growth

3 Where natural recovery takes place, it is probable that as the result of a degree of natural resistance some of the tumour cells die and become absorbed These dying cells are autolysed and their absorption induces an active immunity in the animal, which, in turn, determines the regression of the whole tumour

Conclusions

1 Immune animals inoculated with any transplantable tumour (whether heterologous or homologous) produce antibodies toxic to a wide range of malignant growths

2 The serum alone is, in the case of an animal immunised against a heterologous tumour, lethal to in vitro cultures of the antigenic tumour when sufficient complement is present, but the serum of an animal immunised against a homologous tumour only kills cultures of the antigenic tumour in the presence of leucocytes appropriately conditioned or of some secretion from the latter Thus any malignant cell growing in a rat is, in the absence of leucocytes, quite undamaged by antibodies present in this or any other rat's serum Leucocytes only form their special cytase when extravasated Partial anaerobiosis is probably the factor which determines this

3 The peritoneal exudate (P E H) from a rat immunised against J R S, drawn, say, four hours after a peritoneal injection of J R S *fragments* (or of ordinary broth), always damages or kills in vitro cultures of J R S, but only after a latent period of six to eight hours The peritoneal exudate of a normal rat is toxic only in proportion to the natural resistance of the individual *animal* It often forms an excellent culture medium for J R S cells

4 The clear liquid (P L H) obtained by centrifuging the peritoneal exudate of an immune rat kills as certainly as the whole exudate If this liquid is heated to 56° C for 45 minutes it no longer damages tumour cells It can be reactivated by the addition of peritoneal cells or their secretion, but not by fresh serum even from an immune animal

5 The washed cells (P C H) obtained from such an exudate by sedimentation, together with some of the blood serum (H S) damage or kill cultures of J R S cells Even washed cells from a normal rat when added to the serum of an immunised rat injure J R S cells, though much less severely

6. The immunity of an animal (rat) to a homologous transplantable tumour appears to be due to the combined effect of two factors One of these factors circulates in the blood of an immunised animal and is potentially toxic to many varieties of malignant cells The other factor is exuded by the white blood corpuscles when they have extravasated and are subjected to a low oxygen tension (20 to 40 mm Hg) such as exists in the tissues and spaces of the body Neither of these factors alone is lethal, together they become so, and their toxicity is more or less specific to the implanted tumour which evoked them The most obvious effects they produce (some six to eight hours after their application) are disappearance of the cell *membrane or interface*, and subsequent lysis of the nuclear chromatin Heterologous tumour antisera, on the other hand, contain both antimalignant and anti species bodies, and always kill *rapidly (five to ten* minutes). In this case the cell membrane does not disappear, but its permeability is profoundly altered and chromatolysis follows

7 The tumour cells of all the species studied appear to have something in *common—they* contain a common antigenic substance There is no evidence *that this* substance is a common ætiological factor, it seems more likely to be some cellular constituent common to malignant cells, since by the cytotoxic effects observed the cell itself and not merely its malignancy is destroyed

As on previous occasions, my thanks are due to Prof C J Martin, F R S, for allowing me to work at the Lister Institute, and for continued guidance I am indebted also to many colleagues at the Institute, *and especially to Prof J C G Ledingham*, F R S The British Empire Cancer Campaign, by its grant, has made it possible for me to give my whole time and energy to cancer research. I have to thank my assistant, Miss A C Kohn-Speyer, for her help The staff of the Middlesex Hospital and *Prof* S Russ have again supplied me with human cancerous material

HÆMOPTYSIS OF OBSCURE ORIGIN

A CRITICAL ACCOUNT OF TWO UNUSUAL CASES

BY MAURICE DAVIDSON, M D OXF,
M R C P LOND,
PHYSICIAN TO THE BROMPTON HOSPITAL, PHYSICIAN TO THE MILLER GENERAL HOSPITAL FOR SOUTH EAST LONDON

(WITH ILLUSTRATIVE PLATE)

THE two following cases present features of considerable interest, not *only* in regard to diagnosis, but also to the *treatment* I have thought it worth while to publish them together, partly because they appeared sufficiently unusual to place on record, partly as a subject for commentary and as a text for *discussion of the general mode* of procedure in instances of severe hæmoptysis of doubtful origin *In the second of the two cases, that of carcinoma* of the bronchus, the diagnosis was not made during life, and various useful criticisms may be suggested in view of the *post-mortem* findings, in the first, although the treatment adopted was apparently the means of *saving life*, the *exact* pathogenesis of the condition was and still is a matter of uncertainty

CASE 1 —A S, aged 43, male, a jeweller by trade, admitted *on account of* recurrent hæmoptysis

Past Medical History —Twenty years ago had typhus, *no* other definite illnesses, since the age of 10 has had occasional hæmoptyses, but not during the last six years, *no* cough as a rule except at the time of these attacks, the last attack was on June 22nd, 1925, when he brought up a *pint* of blood

Condition on admission (June 23rd, 1925) —General condition *fair*, well nourished, appears somewhat anæmic, slight cough with coloured sputum, no definite physical sign of disease on examination of the chest, ? slight impairment of resonance at the left apex with diminished air entry, no adventitious sounds heard Heart normal, abdomen normal, C N S normal Temperature 99° F A provisional diagnosis was made, "old tuberculous focus left apex" Subsequent examinations of the sputum for T B were negative (three times), the complement-fixation test for tubercle and the Wassermann reaction were negative

June 29th Hæmoptysis, 12 oz, 30th hæmoptysis, 2 oz After this the temperature became normal for a week, and he remained fairly well

X Ray Examination —July 16th (Fig I on Plate) "Heart shadow enlarged in the transverse diameter, lungs streaky, diminished translucency of right apex, restricted movement of right side of diaphragm There is an opacity at the right base, suggesting some consolidation of the right lung" By August 5th the temperature had become steady and the patient was up for the greater part of the day 6th Hæmoptysis, 18 oz (1 P M), hæmoptysis, 4 oz (4 P M)

ON THE NATURE OF IMMUNITY TO IMPLANTED MALIGNANT TUMOURS . .

DR T LUMSDEN

(*Figures* III A, B, *and* V A, B, *are given in the text*)

UNSTAINED CULTURES OF MOUSE CANCER × 1000

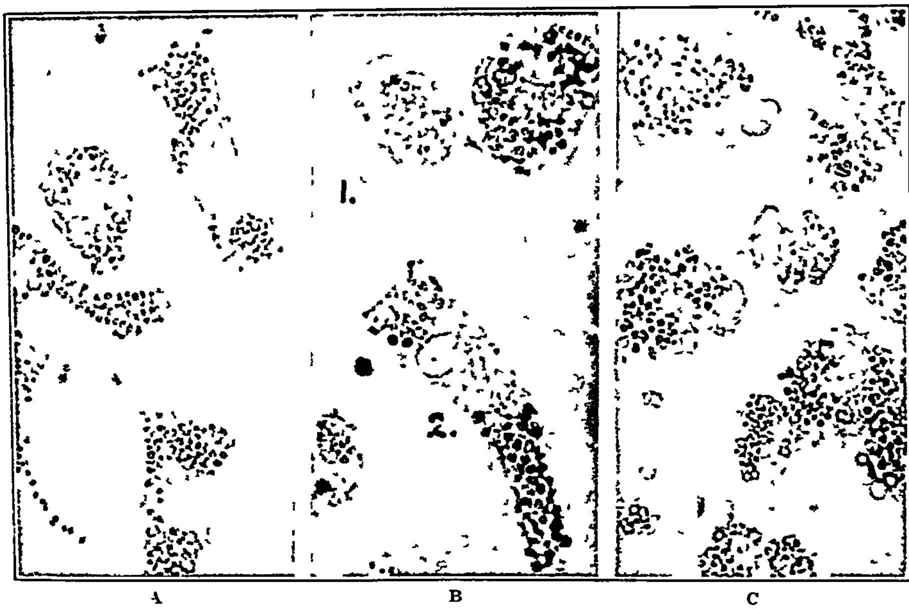

FIG I —A is a culture of mouse cancer (M 63) growing normally in heated peritoneal liquid and fresh serum of an immune mouse Note the clear outlines of the cells and undefined nuclei
B, a similar culture killed by heterologous (rat) anti M 63 serum The fat granules are coarse giving the cells a "ragged" appearance The cell marked 1 shows the characteristic distension of the damaged cell membrane In cell 2 the nucleus has become pyknotic and sharply outlined
C a similar culture killed by application to it of heated peritoneal liquid and a suspension of washed peritoneal cells from an immune mouse The cell membranes have been completely lysed and the whole cell is becoming disorganised

UNSTAINED CULTURES OF RAT SARCOMA × 300

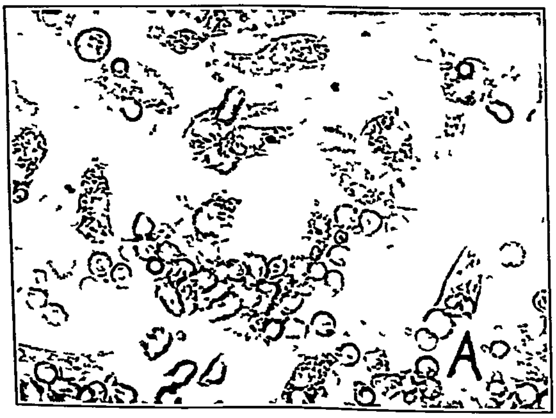

FIG II A —After application of peritoneal exudate from a normal rat Larger and very active cells are sarcoma Small cells some of which are out of focus, are phagocytes

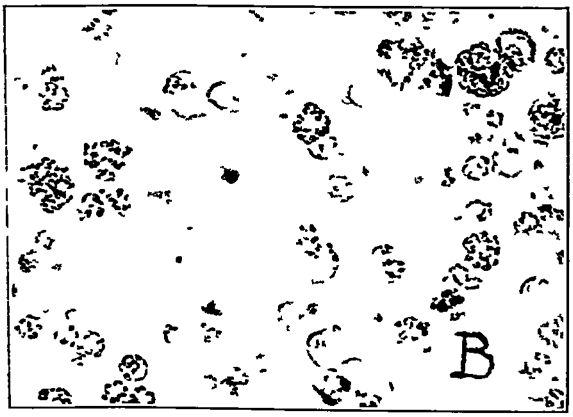

FIG II B —Similar culture in separate drop on same slide after application of peritoneal exudate from a rat immune to sarcoma All sarcoma cells dead and disintegrating

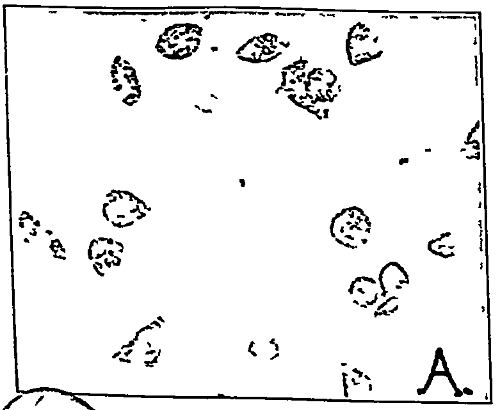

—After application of peritoneal liquid lly prepared) and blood serum from

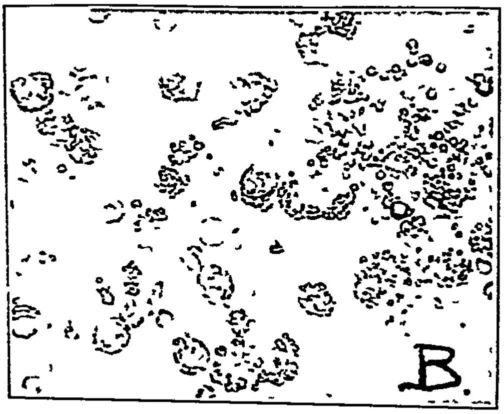

FIG IV B —After application of peritoneal liquid

HÆMOPTYSIS OF OBSCURE ORIGIN.

DR M DAVIDSON.

7th Bronchial breathing and fine râles audible at the left base (patient too ill to be examined very completely) 12th Examined in a sitting position fine râles audible at both bases no appreciable difference in the physical signs between the two sides

From the X ray appearances I concluded that the source of the bleeding was in all probability at the base of the right lung, and determined to attempt an artificial pneumothorax on the right side, this was accordingly begun on August 14th

14th	Induction	−10	−8	650 c cm	−3	− 3
15th	Refill	− 8	−0	600 c cm	−3	+ 6
17th	,,	− 5	+3	600 c cm	+3	+10

19th Hæmoptysis, 4 oz (this occurred in the X ray room just after a skiagram had been taken) Morphine was given and later emetine the hæmorrhage appeared to be controlled to some extent but continued in small amounts

21st	Refill	− 4	+3	100 c cm	−2	+9

23rd Hæmoptysis, 13 oz 24th Calcium lactate, dr 1, given by mouth, followed after two hours by injection under the skin of 5 c cm of hæmoplastin in normal saline 25th Hæmoptysis, 2 oz (11 30 A M) hæmoptysis, 4 oz (2 30 P M), a further 4 c cm of hæmoplastin given

26th Ol terebinth ♏ 20 given by mouth every four hours, on the following day the patient complained of pain on micturition, the urine was acid, albumin was found in fairly large amount, pus cells and some epithelial cells being also present 29th Hæmoptysis 8 oz. My colleague, Mr Tudor Edwards, in discussing the question of operative treatment at this stage, advised that avulsion of the right phrenic nerve in the neck should first be tried This was done under local anæsthesia, about 2½ inches of the nerve being removed, the patient stood the operation well

Sept 1st Examination of the chest showed physical signs of a fairly large pneumothorax on the right side, the heart being well over to the left

5th	Refill	−2	+4	200 c cm	−1	+7

5th Hæmoptysis, 1½ oz (11 P M), 11th hæmoptysis, 1 oz

On Sept 15th two severe hæmorrhages occurred, amounting in all to 34 oz, and the patient's condition became very serious Mr Edwards again saw him with me, and in spite of the desperate state of anæmia and collapse we felt that the only hope of saving life lay in opening the chest in the endeavour to discover and deal with the source of the bleeding, which was still thought to be the base of the right lung The operation was performed under gas and oxygen, an incision, 6 inches long, was made along the fifth interspace on the right side, the pleura was incised, and on exploration it was found that the right side of the diaphragm was completely paralysed and was lying up as far as the third rib, being drawn over to the opposite side with each inspiration The right lung was completely collapsed, the base being adherent to the diaphragm and mediastinum It being obvious that separation of the adhesions would not produce any further collapse of the lung, no attempt was made to interfere with them On palpation the base of the lung itself was hard to the touch and presumably fibrous, the upper zone being apparently normal Two nodular excrescences on the liver were palpable through the diaphragm

DESCRIPTIONS OF FIGS VI AND VII

(*See Illustrative Plate*)

FIG VI —Drawing (high power) of tumour cells from area marked B in Fig V

FIG VII —Drawing (moderately high power) from area marked A in Fig I Illustrating glands in the submucosa from which apparently, the growth originated The early degenerative changes could be seen especially in these in the area marked C

The patient's subsequent progress was uneventful, and except for a very small amount of blood brought up on Sept 20th, no further hæmoptysis occurred

Sept 26th	Last refill	−9	−2	300 c cm	−3	+5

Oct 4th The patient complained of nausea and vomiting with pain and tenderness in the right loin, the urine was found to contain large quantities of oxalate crystals This attack passed off and he made an uninterrupted recovery

Examination of the chest on Sept. 29th showed a hyper-resonant percussion note on the right side in front, with dullness below the level of the sixth rib, breath sounds were absent over the upper part, but could be heard faintly at the base, the heart was displaced to the left At the back, weak breath sounds were audible in the upper third on the right side, over the lower two thirds of the chest there was dullness with absence of breath sounds, ægophony was present just above the level of dullness

On Oct 31st the physical signs were those of fibrosis of the base of the right lung, all signs of fluid having disappeared, and the air in the pleural cavity having been absorbed There seemed to be no necessity for giving any further refills The patient was sent to a convalescent home for a few weeks after which he returned home When last seen on March 18th, 1926, he appeared in perfect health, beyond slight dullness and weakness of breath sounds at the right base there were no abnormal physical signs in the chest

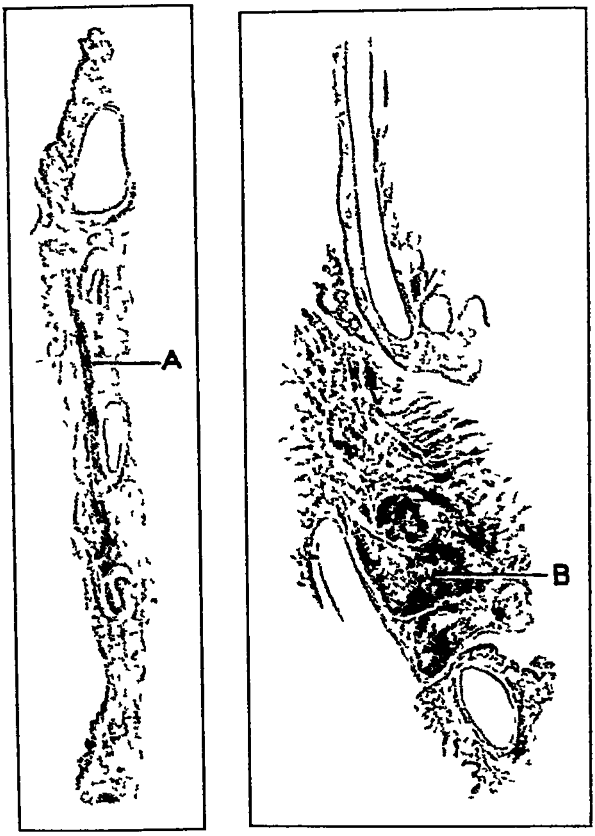

FIG V —Drawings (low power) of longitudinal section of a bronchus B shows tumour projecting from the wall into the lumen

The last X ray (Fig II on Plate) shows the right lung practically decompressed, the diaphragm is high in position, there is no evidence of any fluid

Since writing the above notes I saw the patient again on Nov 1st, 1926 He was still in excellent general health and had had no return of symptoms

CASE 2 —T D, aged 29, male, admitted under Dr Cecil Wall on account of attacks of hæmoptysis

Past Medical History —1915 Rejected from Army because of alleged heart disease 1918 Influenza (*sic*), in bed for five weeks 1919 Bronchitis, in bed for six weeks 1920 Influenza (*sic*), in bed for four weeks 1921 Pleurisy (left side) 1924 Admitted to the Royal Free Hospital with a "heart attack" (dizziness, fainting &c), and while there had a slight hæmoptysis, sent to convalescent home and then returned to work In April 1925, had numerous small hæmoptyses while at work In June, 1925, hæmoptysis, 10 oz, again admitted to the Royal Free Hospital, sputum examined there on three occasions for T B with negative result, transferred to Brompton On admission he was complaining of slight cough with a certain amount of frothy sputum, and occasional pain in the left side of the chest

Condition on Examination —General condition good well nourished Some diminution of movement of the left side of the chest with slight dullness below the clavicle, marked dullness at the base of the left lung in front and behind, with diminished breath sounds vocal resonance, and tactile fremitus, some rhonchi audible on both sides There was no enlargement of the heart, the apex beat was felt in the fourth interspace where a musical systolic murmur was audible, there was some *irregularity of the cardiac rhythm*, due to the interpolation of numerous extrasystoles, apart from the premature ventricular contractions shown in leads I and III, the electrocardiogram was normal Blood pressure 135 (systolic), 100 (diastolic) Examination of the blood gave a doubtful Sigma reaction, the Wassermann and the complement-fixation test for tubercle being negative Three sputum examinations for T B were negative, no mycelium was found, cultures grew *Staphylococcus albus* only

X Ray Examination—Sept 19th (Fig III on Plate) "Heart globular in shape, left border ill-defined, *left side of chest* diaphragm not adherent, but excursion somewhat restricted Relatively lessened translucency at extreme base of the lung, above this is an area globular in shape but of varying density, ? localised consolidation, breaking down, ? localised empyema, ? bronchiectasis"

During the time he was in hospital he remained practically afebrile, with occasional evening rises of temperature to 99°, on several occasions the sputum was coloured, small clots of blood being coughed up mixed with frothy sputum, *the amount of sputum averaged 1 oz per day*

Nov 8th Hæmoptysis, 1 oz 28th X ray examination after introduction of lipiodol *into left bronchus* "No obvious bronchial dilatation, lipiodol appears in a somewhat dense mass, the suggestion being *that there is still* consolidated and fibrous lung, outline of left border of heart obscured"

His general condition improved and he put on 6 lb in weight, no further hæmorrhage having occurred, he was discharged to a convalescent home While at the home he had a severe hæmoptysis of 25 oz, he returned to London after a short interval and was again seen in the out-patient department, the physical signs in the chest were the same as on the first examination, he showed a good deal of pallor

On readmission to hospital it was thought that the introduction of some air into the left pleural cavity might assist the radiologist in his interpretation, and a pneumothorax was induced on March 9th

Jan 9th, 1926	−15	−10	350 c cm	−7	−2
„ 10th „	−13	− 3	200 c cm	−8	−0
„ 11th „	− 8	− 0	200 c cm	−6	+2
		(Hæmoptysis 2 oz)			
„ 12th „	−10	− 2	250 c cm	−8	+1
„ 13th „	−12	− 1	250 c cm	−6	+2

X Ray Examination—Feb 25th (Fig IV on Plate) "*Left lung*—partial collapse, heart apparently not displaced but still globular, the opacity previously noted is no longer seen, thought this may be because it has collapsed, adhesions to chest wall visible"

After the last refill the sputum was free from blood but was somewhat increased in amount, the average being about 5 oz per day, no T B were found after repeated examinations The total leucocyte count at this stage was 5800 per c mm, the differential count showing polymorphonuclears, 73 5 per cent, small lymphocytes, 17 5 per cent, large lymphocytes, 6 per cent, hyalines, 1 per cent, eosinophiles, 2 per cent

The refills were continued at intervals until Feb 10th, when the interior of the chest was explored by means of thoracoscopy The lung surface as seen through the thoracoscope was apparently normal except for a few very fine adhesions, there was no evidence of any extra-pleural tumour formation In view of the increasing amount of sputum during the past few weeks, Mr Edwards, who had seen the patient on the first occasion, agreed that it might be of advantage to paralyse the left half of the diaphragm, and on March 17th avulsion of the left phrenic nerve was performed The nerve consisted of two divisions, one very small, these were removed (about 3 inches in all) A refill of 800 c cm was given on March 21st, and on the 23rd, following a sudden fit of coughing, a large spontaneous pneumothorax occurred, the patient became greatly distressed and cyanosed, and complained of much pain Every attempt was made, by withdrawal of air from the chest on successive occasions, administration of small doses of morphine, stimulants, &c, to tide him over the shock, but his condition became rapidly worse and he died on March 24th

Post-mortem Examination—The heart and great vessels were found to be normal The liver was bulky and finely nodular on the surface, but on section showed no evidence of cirrhosis, microscopic sections showed only slight cloudy swelling The spleen was large, pale, and friable

Lungs The right lung appeared normal, the left lung was collapsed and congested, and was connected with the thoracic wall by one or two tough bands of adhesions On section no gross fibrosis was apparent, although there was a slight increase in excess of the normal fibrous tissue On cutting through the bronchi longitudinally, so as completely to expose the larger divisions, a tumour was found in the first upper division of the left main bronchus For the following detailed description of this, as well as for the microphotographs, I am indebted to my friend and colleague, Dr Norman Ball

"To the naked eye this tumour had the appearance of a simple papilloma covered with blood clot On cutting through it, it was seen that the base was infiltrating the wall of the bronchus, and there was a whitish colour in the deeper parts which suggested new growth. A longitudinal section of this bronchus was made, including both walls of the bronchus and the tumour in the middle of one wall (see drawings in Fig V), the tumour projected into the lumen of the bronchus, partially blocking it, there was no bronchiectasis in the area supplied by this bronchus Microscopically, the tumour is a spheroidal celled carcinoma The cells are rather smaller than usual in this type of tumour but they appear to me to be slightly necrotic The nuclei stain very deeply and the protoplasm is poorly stained In fairly large areas there is very obvious necrosis with karyolysis and breaking up of the protoplasm The tumour is purely local, sections of the neighbouring parts of the lung being quite free from growth There is a fair number of fibroblasts present in and about the tumour"

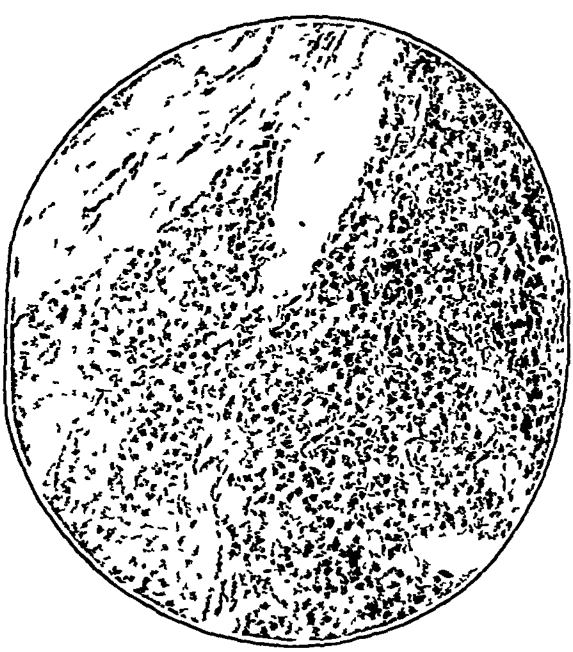

FIG VIII—Actual microphotograph showing a highly magnified view of the tumour

Commentary

The following comments may be made at this point

In Case 1 it will be noted that no attempt was made to X ray the patient after injection of lipiodol The sole reason for this omission was the gravity of the man's general condition and the fear of causing further hæmorrhage by any avoidable movement It is to be regretted that this was not possible as it might have furnished valuable evidence as to the nature of the opacity seen in the first skiagram (Fig I) It was supposed that a small cavity existed in the area indicated by this opacity and that the bleeding came from an arterial branch in the neighbourhood There was nothing in the previous history to suggest any reason for the development of bronchiectasis, and it seems difficult on the face of it to suppose that a bronchiectasis, even of limited extent, which was sufficient to cause hæmoptysis would not have been attended by other symptoms usually associated with the condition The only evidence in favour of early bronchiectatic disease is afforded by the screen examination which showed restriction of the movements of the diaphragm on the right side, a point which is suggestive but not conclusive

As regards Case 2, the obvious point raised by the post-mortem *findings* is the fact that no bronchoscopic examination was made of this patient and that, had this been done, it is possible that the tumour might have been seen by direct vision. The occurrence of the spontaneous pneumothorax is a little difficult to understand. The immediate cause must have been rupture of the lung owing to sudden tension on one of the adhesions which were known to be present The origin of these was presumably an attack of pleurisy from which he was said to have suffered about four years previously The last refill of 800 c.cm given four days after the operation on the phrenic nerve was undoubtedly a large one, but the resulting pressure was not unduly high, although there may perhaps have been a sudden increase in the intrapleural pressure during the fit of coughing which preceded the rupture The radiological appearances in this case are extremely difficult to interpret The skiagrams taken after introduction of lipiodol were not very good films and have not for that reason been reproduced here, but the report of Oct 28th, 1925, should be noted in which it appeared that there was still some consolidation of the lung The only publication I have been able to find that has any bearing on the point is a most instructive paper by Golden, of New York,[1] upon the effects of bronchostenosis upon the Rontgen ray shadows in carcinoma of the bronchus, in which the author demonstrates the changes which may take place in the lung shadows during the course of primary bronchial growths He points out that the hazy, ill-defined shadow seen about the hilum during the stage of invasion may be replaced, as the effects of bronchostenosis begin to manifest themselves, by a dense homogeneous shadow, sometimes accompanied by displacement of the heart and trachea to the affected side Such shadows he considers, are due to atelectasis of the corresponding lobes with associated bronchial and pleural changes and not to the tumour itself. The article is admirably illustrated, and two of the skiagrams shown (Figs. 8 and 9, p 24 loc cit) afford an interesting comparison with Fig. III. of the X rays here reproduced

Differential Diagnosis and Treatment.

I am frequently asked for an expression of opinion as to what should be the general mode of procedure in cases of repeated hæmoptysis in which the cause of the condition has not been established While it is obvious that there can be no golden rule in a matter of this sort and that the details of treatment must necessarily depend upon the diagnosis, there are, nevertheless, problems of a sort afforded by the two foregoing cases in which it seems desirable to formulate in one's mind some sort of general principle in regard to the appropriate order of investigation Into all the recorded causes of hæmorrhage from the respiratory tract it is impossible to enter here. We are concerned for the moment with the type of case in which history and clinical examination have excluded the question of pulmonary *tuberculosis and morbus* cordis as well as those rarer hæmoptyses associated with some general hæmorrhagic disease, and in which the trouble is apparently due to some localised lesion below the larynx The two extra sources of information on which the clinician is largely dependent are the X rays and the bronchoscope, and so far as it is possible to lay down any rough rule for guidance, I would suggest that the investigation should be in the following order First, the complete clinical examination · secondly, X ray examination ; thirdly re-examination by X rays after introduction of lipiodol: and lastly, bronchoscopy The value of lipiodol injection as an aid to radiological diagnosis cannot be overestimated · the technique does not offer any great practical difficulty, and provided the patient's condition does not render absolute rest imperative the use of this method does not appear to be attended with any untoward results The outlining, by this means, of small cavities which cannot be demonstrated in an ordinary skiagram is very definite, and has been strikingly shown in many cases of early bronchiectasis The importance of bronchoscopy in relation to clinical medicine does not appear to be sufficiently appreciated in this country. Chevalier Jackson[2] mentions as one of the indications for bronchoscopy "the appearance in the radiograph of a foreign body *or of any suspicious shadow*" (my italics), and refers to cases of persistent blood-spitting in which endoscopy may afford the only means of deciding the source of the hæmorrhage. It would seem a justifiable principle that in such instances bronchoscopic examination should be made in every case in which no obvious contra-indication exists. Assuming that the source of the bleeding has been localised within the substance of the lung the treatment in most cases resolves itself into a choice of one of the recognised methods of collapse therapy if the hæmoptysis is of such severity or persistence as to render such active interference necessary. Apart from the value of artificial pneumothorax therapy as a mode of controlling pulmonary hæmorrhage it has an additional importance from a diagnostic point of view; the interpretation of a shadow in the skiagram of doubtful significance may be rendered easier by introduction of air into the pleural cavity especially in cases where the question of new growth has arisen The value of diaphragmatic paralysis by phrenicotomy or by evulsion of the phrenic as a mode of treatment is open to criticism, but the method has the advantage that it may often give results which, though insufficient in themselves as a therapeutic measure, yet afford information and give a lead to the surgeon in cases in which the question of a major collapse operation is under consideration

For the X ray reports and for much valuable advice and coöperation I am indebted to my colleague Dr. Stanley Melville

INTRAVENOUS INJECTIONS OF GENTIAN VIOLET IN THE TREATMENT OF RHEUMATIC CARDITIS

By WILLIAM GUNN, M B Ch.B Aberd
LATE HOUSE PHYSICIAN, EAST LONDON HOSPITAL FOR CHILDREN
LATE SENIOR HOUSE PHYSICIAN VICTORIA PARK HOSPITAL.

The value of intravenous injections of gentian violet in the treatment of various blood infections has been studied extensively in recent years in America, but it seems to have been entirely neglected in this country At any rate, as far as the writer is aware, there is no record in our medical literature of the employment of the dye in this manner, though it has been used for the external treatment of septic wounds skin conditions &c.

It has been known for long to have a selective bactericidal action on staphylococci and streptococci, and for this reason I was induced, at the suggestion of Dr G Bourne, of the East London Hospital for Children who had previous experience of the drug to use it in the treatment of rheumatic carditis The assumption that rheumatic fever is one of the coccal group of infections is of course not universally accepted so that the treatment must be regarded as largely empirical.

Historical Note

The action of gentian violet in damaging certain tissues was known many years ago but it appears that Cornil and Babes[1] first found that it possessed a like injurious action on bacteria (1890) Stilling,[2] of Strassburg, published a thesis on the subject: he found the dye a powerful bactericidal agent but failed to find any selective action It was heard of again in 1902, when Drigalski and Conradi[3] discovered that, while it inhibited the growth of cocci and *B coli*, it seemed to have no such effect on *B typhosus* The potential value of the dye in therapeutics was neglected, however, until Churchman began to experiment with it in 1910 He found[4] that the dye is a bacteriostatic rather than a bactericidal agent—i e, it inhibits or retards the growth of bacteria, rather than kills them outright Working with Herz in the Yale Laboratories, he experimented with the dye on rabbits from the point of view of toxicity and bacteriostasis His series[5] of injections falls into two groups in the first group the dye seemed to produce no effect on the animals even when circulating in the blood in a 1/2500 dilution, while in the second group, with the same dosage, all the rabbits went into violent convulsions and rapidly died in opisthotonos Autopsy was usually negative, or, in some cases, showed acute pulmonary œdema Obviously the toxicity of the drug was not the cause, as the same dose was used in all cases, more probably, the rate of injection, resulting in sudden increase of the volume of the blood, is the explanation of the fatalities In the course of the next 10 years Churchman published the results of further experiments with the dye, he produced[6] blood infections in rabbits, and by intravenous injections of gentian violet rendered the blood cultures negative In his most recent article[7] he concludes that, while it is not yet possible to produce a therapia sterilisans magna by these injections, it inhibits the multiplication of bacteria, and thus enables the body fluids and tissues to gain the upper hand As to dosage, it was found that 10 mg per kilo body-weight, given slowly, did not kill, but if the doses were repeated, death was produced at the third or fourth injection

---

[1] Golden R Amer Jour Roentgenol, 1925 xiii. 21

[2] Jackson, C Peroral Endoscopy and Laryngeal Surgery, 1915

The dye was first used[8] on the living subject as an intravenous germicide on July 12th, 1923 The patient had purple vision for six hours, the urine had a blue tint for 24 hours, but no toxic effects were observed, and some improvement followed The second case[9] reported was a child of 15 months suffering from staphylococcal septicæmia with multiple abscesses Three injections were given at intervals of 24 hours, the leucocytosis diminished, the blood cultures were rendered negative, and the child made an excellent recovery Young and Hill published two more cases in the same paper, both suffering from staphylococcal septicæmia, and in both instances the blood was rendered sterile, and general improvement ensued Thereafter gentian violet became reputed in America as a valuable blood antiseptic, and was employed in a great variety of conditions, generally with favourable results Royston[10] found it of some value in streptococcal meningitis, Major[11] used it successfully for subacute infective endocarditis, while Blake[12] combined it with mercurochrome in a case of staphylococcal septicæmia with great success

Both Major and Shallenger[13] report severe cellulitis following spilling of the dye into the subcutaneous tissues with considerable necrosis, and remark that solutions of 1 per cent or over cause thrombosis of the vein at and above the site of injection Hinton,[14] in May, 1925, found the drug of decided value as an adjunct to surgery for staphylococcal septicæmia with osteomyelitis, &c, and recommends its use in similar conditions On the other hand, Brill and Myers[15] published five cases of staphylococcal septicæmia and *B coli* infection, all of which were uninfluenced by the drug and ended fatally The latest publication is by Visher,[16] who treated three cases of encephalitis lethargica and one of chorea with the dye; all four cases were becoming rapidly and progressively worse, and the sudden change on injection impressed him so much that he strongly advised further trials of the drug

Selection of Cases and Methods

When the writer decided to use gentian violet for rheumatic fever, great care was taken that the type of case chosen was such that any effect due to the drug would be fairly easily demonstrated Suitable cases are all too common in children, characterised by smouldering fever, persistent tachycardia, nodule formation, loss of weight, progressive carditis, and lack of response to the usual specific treatment In all the cases selected a fair trial had been already given to the usual measures without definite improvement, and although we know that the rheumatic fires do burn themselves out in favourable cases, any rapid improvement was regarded as being due to the dye

The first difficulty was to obtain a sample of the dye suitable for intravenous use In the first four cases Grubler's preparation was employed, it consists of equal parts of gentian and methyl violet with some dextrin (up to 50 per cent) In the next six cases the sample injected was specially prepared for intravenous use by Dr Martindale, and was practically free from dextrin and metals Injections of both preparations were given to guinea-pigs by Dr S Roodhouse Gloyne at Victoria Park Hospital to determine the effect (1) of single large doses, (2) of repeated smaller doses It was found that as much as 12 mg per kilo body-weight as a single dose, and 5 mg in repeated doses, could be injected without producing any obvious toxic effect—i e, the dye can with safety be in the blood in a dilution of 1/70,000, taking the fluid content of the body to be 70 per cent of the body-weight Churchman and Russel[17] have shown that so low a dilution as 1/20,000 has no obvious effect on growing tissues, while a 1/1,000,000 dilution inhibits the multiplication of staphylococci indefinitely, so that there is a considerable margin of safety in therapeutic doses For the first ten injections into the human subject sterile normal saline was used to dissolve the dye, but as the salt seemed to interfere with the solubility, sterile tap-water was employed thereafter The same dilution—0 25 per cent—was used throughout the series; this dilution does not seem to possess the irritating and destructive effects of the American preparations, for doses up to 5 c cm were injected into the subcutaneous tissues of guinea-pigs without cellulitis resulting, nor was any local effect noted from upwards of 50 injections given to the patients, all of whom, but one, were under 14 years of age The funnel and rubber-tubing method was preferred to the syringe, and only once was it found necessary to cut down upon the vein

Clinical Histories

A brief summary of the histories of seven cases of rheumatic carditis treated by intravenous injections of gentian violet follows —

CASE 1 —D S, a girl, aged 11, suffering from acute rheumatic carditis, had a history of repeated attacks of rheumatic fever and pericarditis two months previously, she made a partial recovery, but nodules appeared on elbows and knees in quick succession Temperature, 97 9°–101° F Pulse-rate, 120–140 Signs of aortic and mitral regurgitation Salicylates failed to affect temperature or pulse rate On April 2nd, 1925, she received 30 c cm of 0 25 per cent solution of gentian violet (Grübler)—i e, 5 mg per kilo body-weight Forehead, lips, and ears were of bluish tint for two hours, temperature was not affected, but pulse-rate fell to 80 next morning, and remained within the 80–100 range A week later 40 c cm were given, frontal headache, restlessness, and insomnia followed, and lasted for several hours, but no untoward symptoms were noted The dye appeared in the urine half an hour after injection, reached the height of output in three hours, and only a faint trace was visible after 24 hours By colorimetric methods it was determined that only 0 75 per cent of the amount injected was excreted in the urine unchanged, the rest being either oxidised or reduced, or stored up in the body tissues Two further doses at intervals of a week were given, the temperature gradually came down to normal, the pulse-rate remained at a low level, the nodules rapidly disappeared, and the patient began to gain weight She was sent to a convalescent home within a month, with a quiet, regular heart and the disease apparently quiescent

CASE 2 —H W, a girl, aged 8, admitted to hospital suffering from rheumatic pericarditis, with large doses of salicylates, the acute symptoms disappeared, but the temperature remained raised (99°–100 5° F) while the pulse-rate never fell below 100 After ten weeks of smouldering fever, during which 30 or more nodules appeared, it was decided to use gentian violet The effect was striking; patient felt chilly one hour after injection, and two hours later the temperature rose by 1½° Next day it fell to normal and remained so for 23 days, the pulse also maintaining a lower level Then slight pyrexia reappeared, and another three injections were given when similar effects were produced The patient did very well and was discharged with the infection apparently arrested

CASE 3 —C R a Jewish boy, aged 9, had subacute rheumatic fever which failed to respond satisfactorily to salicylates The tonsils and adenoids were removed, and immediately the temperature and pulse-rate reached a higher level—averaging 100 2° F and 120 per minute respectively On August 2nd 1925 five weeks after tonsillectomy 40 c cm of gentian violet solution were given The initial chill was followed by a rise of temperature, which next morning fell to normal and remained so for several days On showing a tendency to recrudesce, another injection was given with similar results, the temperature and pulse-rate remained normal, and the patient was discharged to a convalescent hospital shortly afterwards, greatly improved

CASE 4 —W G a Jew aged 13 years, admitted with rheumatic arthritis in a few days developed pericarditis He improved somewhat under the usual measures, but temperature and pulse-rate remained raised, and in the course of a few weeks nodules appeared on elbows and knees Injections of 5 per cent solution of sodium nucleinate were given and raised the leucocyte count from 17,000 to 32,000 cells per c cm, but no appreciable improvement was observed On Sept 4th 1925, 40 c cm of gentian solution were injected, a chill lasting half an hour was followed by a rise of temperature (100 5° F) which disappeared next morning The temperature rose during the day and remained high After an interval of two days another injection was given, definite shivering and bradycardia (60) were followed by pyrexia (102 5°) which disappeared next morning, and the temperature remained down for two days On pyrexia reappearing another injection (50 c cm) was given with like results, but the temperature refused to settle permanently and the injections were discontinued. This patient subsequently received a vaccine obtained from a patient who died of rheumatic carditis, with gratifying results This is the only instance in which gentian violet failed to influence the course of the disease

CASE 6 —J D, a boy, aged 9, came under observation suffering from rheumatic pancarditis, he was pallid, puffy, dyspnœic, and slightly cyanosed The signs pointed to pericarditis with left-sided pleural effusion, improved under usual measures, but a relapse occurred and condition became critical, dyspnœa and cyanosis reappeared, legs and chest wall became œdematous, anorexia and intractable vomiting seemed likely to usher in a fatal termination, when a small dose—30 c cm.—of gentian violet solution was given. It was considered inadvisable to inject more fluid at one time into the circulation on account of marked cardiac dilatation In all, six injections were given, one had to be stopped half way through on account of vomiting This was the only case in which difficulty was experienced with the later injections on account of thrombosis of the arm veins The patient improved slowly, but ultimately made an excellent recovery

CASE 9 —E P, a girl aged 10, was admitted suffering from her third attack of chorea, the heart showed the early signs of mitral stenosis nodules appeared on both elbows, and while there was little or no fever, the pulse was persistently accelerated She received four doses of gentian violet at intervals of a week, there was an appreciable reaction on only one occasion, but the pulse-rate gradually lowered and the infection seemed to quieten down from the injections. She was discharged without any symptoms, and with a quiet and regular heart

CASE 10 —M A, a girl aged 5 years, with a history of rheumatic infection for over a year, showed subcutaneous nodules on elbows and knees, a deformed chest wall a loud presystolic murmur with marked thrill, and definite rib-recession on systole She was somewhat dyspnœic and showed marked bronchitic signs A small dose—25 c cm — of gentian violet was injected into the median basilic vein On withdrawing the needle the child was observed to collapse the eyes became staring and were rotated upwards and to the right, the face became blue and congested the jaw was fixed and the limbs went into convulsive movements The vein was opened immediately with a scalpel, but the flow of blood was disappointing the breathing stopped and the pulse became imperceptible The external jugular veins were noticed to bulge and the right vein was opened Violet-blue blood flowed copiously, and about 30 c cm were removed The result was immediate and striking, the twitchings ceased, respiration was resumed and, in a minute or so the patient was crying vigorously The wound healed rapidly and the patient seemed to improve for a short time, but died six weeks later from cardiac failure

This experience recalls the results of Churchman's injections in rabbits of the second group, and probably the same explanation holds good That the collapse was due to the sudden increase of fluid in an already weakened heart is supported by the rapid recovery consequent upon removal of that fluid On the other hand, there is some evidence that a "shock" reaction, somewhat similar to protein shock, may be produced by introducing non-protein substances into the circulation The question of impurities as the causal factor has been studied in connexion with the use of salvarsan and its allies It is well known that a similar reaction is occasionally produced when 606 is prepared with tap-water, and absent when distilled water is used In the instance just described tap-water was employed, as in upwards of 40 injections given to some of the cases in the series This is the only case in my series in which definitely toxic effects were observed, but I have been informed that fatal results have followed the use of gentian violet in similar conditions In the cases in question the prognosis as to life was hopeless, but the employment of the dye undoubtedly precipitated the fatal issue, apparently by acting as a protoplasmic poison Some caution should therefore be exercised in the dosage of the drug and the type of case treated, though the American literature does not seem to contain a hint of possible risk

Summary and Conclusions

1. The available literature (entirely American) on the use of intravenous injections of gentian violet is reviewed and the results examined

2 Details are given of seven of my ten cases of rheumatic carditis treated by gentian violet

3 The failure of tonsillectomy or so-called specific treatment to prevent or control the rheumatic infection is clearly shown

4 With moderately careful technique, the method is safe and easy, and leads to few, if any, ill-effects; thrombosis of veins occurred in two cases, vomiting in one; no instance of cellulitis or sepsis was encountered

5 Of my ten cases, eight were definitely improved, one was apparently uninfluenced, while one case did not receive a fair trial

6 From an examination of the results, it may be reasonably concluded that gentian violet opens a more hopeful future in the treatment of blood infections, and is worthy of a more extended trial

All the cases were in-patients of the East London Hospital for Children, or of Victoria Park Hospital, and the writer begs to acknowledge here his thanks for the encouragement and consideration which the honorary staff invariably showed him, and for their kind permission to publish these cases

THE LATE DR G M HIRONS —The death is announced of Dr George Merriman Hirons at Bournemouth, at the age of 82 Dr Hirons was educated at the Anderson College and the University of Glasgow and took the Scottish triple qualification in 1872 He held appointments as resident physician at the Glasgow Royal Infirmary and as house surgeon at Teignmouth Infirmary On going into practice at Bournemouth he became one of the first magistrates appointed for the county borough and was later elected mayor

Clinical and Laboratory Notes.

A CASE OF MENINGITIS

WITH EXAMINATION OF THE CEREBRO-SPINAL FLUID

By Duncan Macmillan, M D Edin., B Sc ,
LATE HOUSE PHYSICIAN, DEVONSHIRE HOSPITAL, BUXTON ,
AND
Joseph Race, F I C ,
BIOCHEMIST TO THE HOSPITAL

The record of this case is of interest on account of the fairly complete examination of the cerebro-spinal fluid removed by lumbar puncture

The patient, a boy of 18 and a barber by trade, was admitted to the Devonshire Hospital, Buxton, on April 21st, 1926 He gave a history of having had an attack of influenza ten weeks previously After recovery the knees became painful and swollen, red painful nodules appeared on the limbs, and he had to return to bed He had been going about for some three weeks before admission to hospital

On examination he complained of stiffness in the knees and feet, of pain on walking, and of painful red nodules on the arms and legs He was an anæmic, overgrown youth , the muscles of the left calf were tender to pressure , there was a mucopurulent discharge on the posterior pharyngeal wall , and the urine contained a trace of albumin He was sent into hospital with a diagnosis of post-influenzal rheumatism

After a week of routine hydrotherapeutic treatment the patient complained of increased pain in the arms and legs His temperature was found to be 99° F and he was put to bed During the next few days the temperature ran a very erratic course, one evening being as high as 104°, and although he was slightly drowsy and showed a slow reaction-time he felt fairly well and wished to get up On May 5th he had persistent headache and vomited twice The next day he developed photophobia and stiffness of the neck and Kernig's sign was present By lumbar puncture 45 c cm of turbid fluid were obtained which gave a cell count of 40,000 per c mm with about 90 per cent polymorphs Samples were submitted to the pathologist who reported them to be sterile

Antimeningococcal serum was given intrathecally, about 260 c cm being given in all Lumbar puncture was done twice daily for ten days and then once daily for nine days On May 12th there was marked papillœdema and the patient was in a semi-comatose condition with definite head retraction One to two pints of saline were given daily by the subcutaneous method The patient began to improve and after many relapses became quite clear mentally with a steady temperature He was discharged on June 15th No meningococci were detected in a throat swab and the Wassermann test gave a negative result

On August 28th his doctor reported that he showed no signs of meningitis He was then still in bed, very thin, and had contracted knee-joints which were loosening under treatment At the present time (January) his condition is materially the same He has a definite arthritis but no meningeal symptoms

An analysis of the cerebro-spinal fluid gave the following results

Analysis of Cerebro-spinal Fluid

Date	Total nitrogen	Uric acid Benedict	Urea nitrogen	NaCl	Glucose	Inorg phosp	Calcium
—	%	mg %	mg %	mg %	%	mg %	mg %
May— 10th	0 090	1 66	11 4	575	0 035	3 77	6 98

18th	0 132	1 70	9 6	620	0 027	5 13	6 75
19th	0 072	2 00	12 6	630	0 028	4 43	6 60
20th	0 155	2 14	11 5	570	Trace	4 28	6 54
22nd	0 059	1 88	11 1	650	0 048	4 15	6 06
24th	0 063	1 84	10 9	600	0 045	5 27	5 86
28th	0 044	2 08	12 6	570	0 061	5 54	6 25
June— 8th	0 060	—	—	—	0 060	—	—

May 10th Diffusible Ca 7 08 11th Cell count 30,000 15th CO_2 content 49 per cent 18th CO_2 content 44 per cent 22nd Cell count, 810 , albumin, 0 146 per cent , globulin, 0 116 per cent , N P N , 0 017 per cent 28th CO_2 content 50 5 per cent , cell count, 20

The results on the whole are typical of an acute meningococcal meningitis, although a few of the figures for sodium chloride are so low as to suggest a tuberculous infection It may be of interest to note that the cerebro-spinal fluid on May 22nd gave a strongly positive reaction with acetic anhydride and sulphuric acid (Harris test for paresis),[1] whilst it was quite negative on June 8th This suggests that this test, like the colloidal gold reaction, is dependent upon an abnormal ratio of albumin to globulin

We are indebted to Dr J E Harburn for permission to publish these notes

A CASE OF CANCER OF THE BREAST

WITH AN UNUSUAL SEQUEL

By W G Evans, M B Lond , M R C S Eng ,
HOUSE SURGEON, ST. MARY'S HOSPITAL, LONDON

The following case appears worth recording

Mrs M , aged 56, was admitted to St Mary's Hospital, London, on account of a lump in the breast which had been present for three months Her left arm had lately begun to swell Her general condition was good apart from a secondary anæmia A lump having all the usual signs of a carcinoma occupied the axillary tail of the left breast , it was fixed to the pectoralis major, and the skin overlying the lower and outer quadrant of the breast showed typical *peau d'orange* infiltration The axilla contained several hard glands

On Sept 25th, 1926, Mr Duncan Fitzwilliams performed a radical operation, during the course of which it was found that a mass of infected lymphatics passed from the growth to the axilla and along the axillary vein Together with the whole of the axillary fat and glands this was removed en masse by gauze dissection The disease was found to be much more extensive than had been suspected Four days later the patient's breast-flap began to be discoloured and the suture line gaped A course of four injections of colloidal lead was commenced On Oct 5th the flap sloughed right off, exposing intercostal spaces covered with weak granulation tissue When the raw area had been cleaned for a week with hypertonic saline dressings, an attempt to approximate the edges was made under gas and oxygen anæsthesia On Oct 26th the patient was apparently doing well, but in the early morning of the following day she suddenly felt acute pain and became collapsed Her pulse was imperceptible, a swelling appeared above the symphysis pubis, and the left labium became enormously distended and fluctuant The foot of the bed was raised and morphia given She improved in a few hours and the swelling subsided and seemed to pass backwards into the perineum The skin showed later a purple discoloration over the labium in front of the pubes The next day a similar attack occurred, but with no swelling The treatment was repeated and hot saline was given per rectum The heart-rate was 150 a minute, though the pulse was imperceptible

No diagnosis of the cause of the trouble was reached, but later it was suggested that a retroperitoneal hæmorrhage had found its way through the inguinal canal and caused the swelling in this area There was, however, no sign in the abdominal cavity either of hæmorrhage or free fluid

On the following day (Oct 28th) at 3 30 A M there was marked air-hunger, restlessness, slight abdominal distension and dullness in the flanks The pulse could not be felt and the patient died in a few minutes

Post-mortem Examination —Externally a large hæmatoma of the labium was seen to extend down the canal of Nuck On dissection the third, fourth, and fifth intercostal muscles were found to be completely replaced by new growth, though covered with apparently healthy granulation tissue The underlying pleura was studded with nodules of new growth, and the lung was so collapsed that it sank in water On opening the abdomen a pint of fluid blood was removed large clots surrounded the tail of the pancreas, which, on section, was full of new growth that had spread directly along the lymphatics traversing the diaphragm from the diseased pleura In the tail of the pancreas the growth had softened and eroded the splenic vein, thus giving rise to recurrent intraperitoneal hæmorrhages, and finally causing death The subcutaneous hæmatoma was due to blood tracking along the canal of Nuck to the perineum

The interest of the case lies in the unusual method of spread by direct extension along lymphatics to the pancreas and in the curious clinical features which were so puzzling till the definite signs of internal hæmorrhage gave a clue to the condition Injections of colloidal lead sometimes causes softening of carcinomata, and it is just possible that the softening was due to this treatment

I wish to thank Mr Fitzwilliams for his permission to publish this case

A NOTE ON COMBINED AMNESIA.

BY CORNELIA WINTER, M B , CH B EDIN ,
HON ANÆSTHETIST, GENERAL HOSPITAL, WOLVERHAMPTON

LOCAL anæsthesia has now been established as a safe and reliable procedure, and the surgeon can confidently assure his patient that he will feel no pain The patient, however, especially if he is nervous or has had much pain previously may not share his confidence, and consequently may go through a good deal of mental suffering

An attempt has been made both to determine the stages of anæsthesia in which, when painful stimuli have been abolished by local injection of novocaine solution, a complete amnesia is produced, and to assess the advantages of such methods of anæsthesia The subjects of the test were patients requiring nasal operations In each case the nose was sprayed with cocaine hydrochloride (5 per cent solution in adrenalin) Two minims of this solution were sprayed into each nostril every five minutes, this being done three times, and anæsthesia for all ordinary purposes was produced after half an hour Such anæsthesia was found to last for one and a half hours, and if during this time the patient was made to inhale the vapour of chloroform-ether mixture (one part chloroform, two parts ether) it was found that he lay relaxed and motionless while the operation was performed The mixture was breathed until he could no longer repeat numbers spoken by the anæsthetist, and the degree of chloroform-ether anæsthesia reached was that of the first stage of surgical anæsthesia Where an operation was designed to last for more than three or four minutes the amnesia was continued by dropping ether on several layers of gauze covering the patient's mouth The patient was able to carry on a conversation within three or four minutes of the end of the operation Shock was markedly absent and post-anæsthetic vomiting did not occur

At the beginning certain difficulties arose Thus if the patient passed beyond the first into the struggling stage of surgical anæsthesia, complete anæsthesia had to be produced In seven cases the patients spoke during the operation but none of them afterwards remembered anything of the operation Cases were not always satisfactory in their return to consciousness One patient, for instance, still felt the effects of the anæsthetic after sleeping for three hours. The vast majority of subjects however, recovered consciousness at once and remained conscious, suffering no ill-effects whatever from the anæsthetic About 80 cases have been treated in this way, and as our knowledge of the technique of administration grows the above difficulties tend to disappear

---

MESSRS J and A. Churchill announce that a second edition of Prof A J Clark's Applied Pharmacology" will shortly be published A second edition of "Synopsis of Hygiene," by Dr W W Jameson and Mr F T Marchant, is also ready and is said to incorporate all the regulations which have recently come into force

THE King has sanctioned the following promotions in and appointments to the Venerable Order of the Hospital of St John of Jerusalem Major Sir John Lumsden M D , to be Knight of Justice , Lieut.-Colonel Evan James Trevor Cory, M D to be Knight of Grace , and Dr Marcus Antonius Johnston de Lavis-Trafford, Dr Albert Reginald McLeod, Colonel Richard Arthur Needham, I M S Dr Louis Patrick Stokes Major Hugh Tener Galbraith F R C S and Dr Robert Douglas Argyll Douglas to be Officers (Brothers)

Medical Societies.

MEDICAL SOCIETY OF LONDON.

CHANGES IN THE CLINICAL ASPECTS OF DISEASE

A MEETING of the Medical Society of London was held on Jan 10th when SIR HUMPHRY ROLLESTON gave a presidential address

Everyone recognised, he said, that the common epidemic diseases showed variation from year to year in the degree and prominence of certain characters and manifestations. What was called "influenza" might in one year be mainly nasopharyngeal, in others it was pulmonary, gastro-intestinal, or nervous, or from the presence of a rash it imitated scarlet fever. The fact that a familiar disease might suddenly change its character and become very virulent made the subject of variation of immediate practical importance It might be argued that what were called types of influenza were really distinct diseases On the other hand, Sir William Hamer had for years believed in the epidemiological relationship of diseases associated with different microbic agents and had regarded influenza, cerebro-spinal fever, acute poliomyelitis, and epidemic encephalitis as variants of the same morbid process Referring to these and other diseases Hamer had written: "Surely we may recognise the protean influenza, now merely in mufti, but changing from one civilian garb to another under our eyes, and demonstrating unmistakably that the more it changes the more it is the same thing" Later he had suggested that in pandemic times the virulence of the influenzal germ was different from its activity in the intervals or trailing prevalences, in pandemics it gave rise to a shock-attack or influenza, but in the intervals it was apt to activate various secondary or associated micro-organisms such as pneumococci, streptococci, and meningococci This was much less iconoclastic than the view that all these diseases were due to modification of the same micro-organism

Examples of Change

A number of diseases, continued the President, were known to have changed their clinical characters, thus scarlet fever had been very mild a century ago, 50 years ago it had been extremely malignant, and now again it was a mild infection The clinical differences were perhaps due to infection by differing types of the strains of *Streptococcus hæmolyticus* and it might be that whereas simple mild scarlet fever was due solely to pure streptococci, the malignant forms were a result of secondary infection Acute rheumatism had become less acutely arthritic, though not less common Thoracic complications were now very rare in this disease, a change possibly connected with alteration in treatment—venesection in the past and salicylates during the last 45 years Secondary infections might have been favoured by the length of the illness in pre-salicylate days Acute and tophaceous gout was becoming a curiosity, a change attributed to temperance Pneumonia had considerably altered its character since the reappearance of influenza in 1889, broncho-pneumonic forms being now, perhaps as frequent as the frank lobar form: but this was only to say that there were several forms of the disease The mortality varied also according to the type of pneumococcus The character of small-pox had been changeable in the past and mild epidemics had been noted by Sydenham, Jenner, and others Some regarded the disease now prevalent as distinct from small-pox and would like to give it a separate name There were good grounds however for thinking that it was a mild form of small-pox due to a virus with suppression of its toxic properties for man, its affinities for other animal species not being appreciably changed. It occurred almost solely in the unvaccinated and protected against small-pox and vaccinia; experimentally the viruses of the three diseases had been shown to be variants of the same virus As a rule, though not invariably, the mild form bred true, but the mild and severe forms of small-pox might occur side by side The objection to employing a special name was that it might make it even more difficult to maintain the necessary preventive measures of vaccination and isolation

Acute appendicitis, said the President, had undoubtedly become very much commoner since 1889, when influenza broke upon this country after a respite so long that its nature was not recognised for some little time Had it been as frequent before its operative treatment came in as it was now, the mortality from acute peritonitis in those days would have been very high To explain its increased occurrence various factors had been suggested, such as alteration in diet, great consumption of meat—fresh, frozen, or tinned—fresh fruit and antimony from the red rubber of bottle-stoppers The association with the return of influenza which had an intestinal form, was certainly significant

Amongst comparatively recent changes in chronic disease, said the President, were the great diminution of chlorosis—to be contrasted he believed, with an increased incidence of pernicious (Addisonian) anæmia —and an apparent reduction in the occurrence of urinary calculi Syphilis when it broke out in a previously uninfected race, was much more virulent than in civilised and syphilised countries, but the much milder type of the cutaneous and bony lesions of syphilis in this country could hardly be ascribed solely to some approach to relative immunity for, like other diseases, syphilis had been modified by early recognition and treatment Such treatment might in part explain why the terrible tertiary lesions of bone were now seen so seldom, and in the same way prophylactic and curative measures had done much to abolish enteric fever and had robbed diphtheria of many of its terrors Early operation for perforated or leaking gastric ulcer had made gas-containing subphrenic abscesses extremely rare, and the character of cases of gall-stones had undergone some change owing to earlier operation in cholecystitis In Paris, at any rate, stones in the common bile-duct had become uncommon

Variable Resistance of the Host

It would be strange, indeed, the President went on, if diseases always remained the same, for they must vary both with the cause and with the host—the seed and the soil The effect of a virulent micro-organism's attack was influenced by the resistance of the individual, and as Prof W W C Topley and Prof Major Greenwood were showing,[1] the spread of an epidemic depended also on the susceptibility of the herd as a whole Through secondary infections, moreover, the part played by bacteriophages and by diet might possibly affect the relations between the parasite and the host That continued exposure might be followed by a greater or less degree of immunity in exposed persons was suggested by the increased resistance of laboratory animals which had survived an epidemic, by the growing immunity of schools and institutions to diphtheria and to scarlet fever, as shown by the Schick and Dick tests, by the fact that natives in the tropics acquired immunity to malaria and yellow fever, and, indirectly, by the severity of epidemics of measles among the inhabitants of isolated countries, where the disease rarely occurred

Though the long persistence of epidemic diseases, especially measles, showed that time produced little racial immunity, L T Webster had brought forward experimental evidence of its development, and there were clinical grounds for thinking that an increase occurred during long periods Changes in the constitution or make-up of the members of a race must also exert some influence on the liability to special diseases, the Jews, for instance, were particularly prone to diabetes mellitus, obesity, and arterio-sclerosis Environment, hygienic conditions, alcoholism, and food-supplies influenced the general resistance and so the susceptibility to disease It would be interesting to know which of the two factors, the variations in the host's resistance and the pathogenic power and the dosage of the microbe, was more important in the production of infection In human disease it seemed reasonable to anticipate that impaired resistance would play a more dominant part than microbic fluctuations in favouring infection The increased frequency of subacute and chronic bacterial endocarditis raised the question whether this could be correlated with correspondingly great incidence of focal infections—dental, tonsillar, or intestinal—which were in turn due to a widespread diminution in resistance allowing micro-organisms (e g, strains of streptococci) usually saprophytic to become pathogenic The definite increase of subacute and chronic bacterial endocarditis, especially in ex-Service men, since the war, with its infecting and depressing conditions, was an argument in favour of the view that a diminished resistance was the probable responsible factor. War might so reduce the resistance of the nations that diseases not usually prevalent or sometimes previously unrecognised came into prominence In Russia, for instance, during the late war rickets, hunger œdema, famine cachexia, acute enteritis, and peptic ulcer, and typhus and relapsing fever (immediately due to animal vectors) had become rampant Tuberculosis had increased in all the combatant European nations In Germany and Austria rickets had become extremely common, and keratomalacia and blindness appeared, in Germany there had been an increase of jaundice and acute yellow atrophy Epidemic encephalitis, practically a new disease, had been described by Economo in Vienna in 1917, and soon, like influenza, had spread over the world The conditions of stationary warfare had created trench fever and trench nephritis and made spirochætosis icterohæmorrhagica common instead of a curiosity But these conditions were chiefly an outcome of circumstances favouring mass infection, and not, in the main, the outcome of changes in the resistance of the troops

It was tempting, said the President, to associate with " the wear and tear of modern life " an increase of functional and organic nervous diseases, of diabetes high blood pressure, and arterio-sclerosis, but it was difficult to be certain—probable as it might seem—that neurasthenia and functional disease were much commoner now than in the past It was impossible to be certain that there had been an increase of high blood pressure, and arterio-sclerosis had been common in ancient Egypt

Variations of Bacteria

Variation and mutation, said the President in conclusion, were more readily and rapidly produced in bacteria than in higher animals and man, and serological research had shown the perplexing problems which might arise from them He instanced *Bacillus paratyphosus* B and *Bacillus aertrycke* as organisms culturally and morphologically indistinguishable yet serologically different, and also distinct in their clinical effects, the first causing paratyphoid fever and the second acute food poisoning Virulence, moreover, might be modified by environment, nature of nutrient material, temperature, and possibly other factors Changes in the clinical aspects, for example, of enteric fever and cerebro-spinal fever, might be due to infection with different types of the typhoid-paratyphoid group and of the meningococcus It was reasonable to believe that further evolution of such varieties might be accompanied by such alterations in the clinical picture as to constitute new diseases, as, indeed, had occurred in the differentiation of typhoid and paratyphoid fevers The adaptability of bacteria to altered conditions so that a harmless saprophyte living on the surface of the body could be changed into a pathogenic micro-organism had been emphasised by the late Prof J G Adami, who had given as a probable example the transformation of some previously harmless diphtheroid bacillus into the virulent diphtheria bacillus, to account for the appearance at the beginning of the last century of diphtheria, a disease so sharply cut that it could hardly have been overlooked by all physicians until Bretonneau of Tours gave his classical description in 1821 Among animals hog-cholera, unknown before the 'sixties, when it appeared in the United States, was another example in support of the view that bacteria could and did undergo evolution from a saprophytic to a pathogenic state

---

[1] THE LANCET, 1926, i, 477, 531, 645

Discussion

Dr E M **Callender**, proposing a vote of thanks to the President, said that it was now 30 years since he had seen one of those severe cases of syphilis which began with high fever and went on with periostitis affecting several bones, profuse eruption, and profound illness He was also well aware of the changes in virulence of influenza, and recalled an occasion in France in 1918 when 35 men who had been brought in suffering from influenza died in the night

Sir **Charles Ballance**, seconding the vote, referred to the immense debt the profession owed to Sir Humphry Rolleston for his intellectual activity Going on to speak of the advantages of vaccination, he said that in Egypt alone 60,000 children died of small-pox yearly before vaccination was introduced He clearly remembered a lecture given by Dr. Charles Murchison, the greatest clinical teacher he had known, when he was Murchison's clinical clerk That was about 1878, and the subject was Fatal Cases in which Pus is Found in the Neighbourhood of the Cæcum , yet at that time there was no suggestion in London for operating on the appendix, and despite the fact that Liebert, in his "Pathological Atlas," had well illustrated the subject of appendicitis and given a clinical description of it, he had not suggested operating for its relief As regards the changes in syphilis, he thought that even after modern methods of treatment there could still be late sequelæ of the disease, such as locomotor ataxia

The **President** replied to the vote of thanks, and invited Sir William Hamer to take part in the discussion

Sir **William Hamer** agreed with the President's view that medical men were now beginning to realise that they were not dealing with diseases, but with the reaction between the germs and the human body —a conception which had been rather lost sight of in the gathering of so much information about the germs themselves Medical men of the eighteenth century had been clear in their idea that they were dealing with the results of this reaction, as were Sydenham and Willis 100 years before them Sydenham, in his medical observations, talked of infecting particles in the air and the crises and the humours, and said that the latter were only concerned in so far as the infecting particles in the air had influenced them The difference of symptoms and manifestations in epidemics was due to the differences in the reactions of persons In his chapter on fevers, Willis was even more explicit In 1657–58, which was a year of influenza, he attributed the outbreak to infecting particles in the air, but realised that this was not a sufficient explanation—that there had to be, to produce the symptoms a reaction on the part of the human body to those particles

Sir **Percy Bassett-Smith** spoke of the changes observed in the character of Malta fever In former days, when the wards were full of the disease, the patients had acute sweats and painful arthritis, accompanied by a good deal of neuritis, so that morphia had to be freely used to mitigate their sufferings Nowadays arthritis of severe degree was seldom met with, and the type of the fever was not so severe as formerly In the cases described as occurring now in South Africa, Italy, and the South of France, there was a much greater tendency to hæmorrhagic complications and to slight meningeal involvement neither of which had been much heard of in earlier days Thus in 30 years the disease had shown a great change in the chief manifestations In countries where the disease was common the carrier of the infection had also largely changed In the Italian and French Riviera the carrier was the sheep more than the goat, while in Italy and South Africa the carrier was now the cow In America, too, the type of disease seen was chiefly attributed to cattle There was a very close likeness between the organism formerly found in goats and that now found in cattle and sheep, and it was highly probable that in its passage through animals which did not actually suffer from the disease the organism had undergone some modification of its virulence, and consequently caused a modified disease in infected human beings Typhus had been a very fatal disease, but in the tropics there was now a typhus which had practically no mortality , it caused an eruption, lasted 14 days, and then disappeared Why was this ? The two diseases could not be called separate for they had much in common

Mr **Zachary Cope** said that by asking a medical man whether he had seen certain diseases or what kind of cases he had seen, it was almost possible to tell at what period he qualified Extravasation of urine, enlarged glands in the neck, and ulceration in chlorotic women had become rare during the last 20 years On the other hand, cancerous and other degenerative conditions following the over-use of irradiation were a recent manifestation, and it was not impossible that in the future cases of violet-ray epithelioma might have to be faced

Dr H A **Des Vœux** said that he doubted whether the President was right in his suggestion of a relationship between influenza and appendicitis Influenza had been known for 400 years, and the name had been given to it by a London physician who said that it flowed all over England, from the King in his palace to the peasant in his cottage If it had been a cause of appendicitis the latter would have been earlier and better known, though it had been recognised, he thought, earlier than was usually supposed In earlier days appendicitis generally resulted in acute peritonitis, a condition now very uncommon Many people had periodic attacks of appendicitis which quieted down, and he knew a lady, aged 86, who had had chronic appendicular attacks for 45 years and had never been operated upon So-called bilious attacks, with abdominal pain, seemed now to have largely died out , they were probably due to appendicitis

Dr F **Parkes Weber** said that one of the great difficulties in discussing the subject was the change in the names given to diseases, but a still greater difficulty was that the same name had been used at different periods for different diseases Before the war a disease, not very rare, was described as occurring in Australia in epidemics and was described by Dr H Smith as erythœdema , he had said that it was characterised by redness and pain in the extremities. Then the name had been given to a disease characterised by redness and swelling in the extremities and later papers had been contributed speaking of cases of redness and pain in the extremities as erythromelalgia Acrodynia was another name which had been given to more than one condition ; that to which it was now applied did not correspond to the disease which, under the same name, created such an impression in France 100 years ago

---

A Novel Contributory Scheme —A scheme has been established in a Bradford factory under which the workers pay 1s per annum each to ensure in-patient treatment at the Bradford Municipal General Hospital It is actuarially calculated that this small contribution will be sufficient to meet the fees which would be charged if the men went in as private patients The Health Committee of the Corporation have accepted the scheme and it is hoped to extend it to other factories Indeed, it is being proposed that these facilities should be offered to all and sundry at the same price Dr J T Buchan, the medical officer of health for Bradford gives it as his belief that sooner or later, the public will ask for some such arrangement

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF COMPARATIVE MEDICINE AND TROPICAL DISEASES AND PARASITOLOGY

A combined meeting of these Sections was held on Jan 5th, Sir D'Arcy Power, President of the Section of Comparative Medicine, in the chair.

Dr W. H Andrews opened a discussion on

Trypanosomiasis in Man and Animals

He spoke of the simplicity of early classifications and the maddening complexity which had followed He regarded the recent tendency to group and simplify, particularly the work of Wenyon as a sign of progress Classification was very difficult and was impossible on morphological grounds alone, but the introduction of biological characters into the scheme of classification was very unsafe The mode of development in the fly appeared to be stable, but such characteristics as virulence to particular species were of very doubtful value Even the morphology was not absolutely fixed There was constant difficulty in trying to see order amidst the chaotic masses of facts It was doubtful whether the effects of artificial propagation from mammal to mammal were the same as those of mechanical transmission in the field The speculation was fascinating but many facts seemed to argue against it The *T brucei* as originally described by Plimmer and Bradford was now unknown Probably the organism was polymorphic and had taken on that particular monomorphic form as a result of repeated inoculation in the laboratory The whole question of virulence was one on which much more information was needed In many cases cattle harboured trypanosomes without suffering any harm and formed reservoirs, yet at times there would be serious outbreaks of disease among them from the same organism In some cases age appeared to be a factor as well as the strains of host and organism The effect of the mammalian host on the parasite might be very considerable There was no direct evidence of such an effect on trypanosomes, but the ultramicroscopic virus of African horse-sickness, for example, might be found on recovery from inoculated animals to have undergone sudden increase in virulence or to be much weaker Continued observations were needed on the difference between mechanical and cyclical transmission and their effects on virulence Parties of men and animals were constantly going up from Natal to Zululand, they lost dogs and horses, and many animals still harbouring the parasite must return with them, yet trypanosomiasis was never brought down to Natal The only case of naturally occurring *T gama* infection the speaker knew of was in a laboratory dog which had eaten the carcasses of artificially infected guinea-pigs If the work of Cross and Patel could be confirmed, it would be recognised as one of the most important pieces of investigation ever done in this field

Prophylaxis

The importance of domestic animals as reservoirs must not be forgotten, continued Dr Andrews The objections to destruction of game arose from sentiment, from fear of making the organisms concentrate on man, and of scattering the game (and with it the fly) by large hunts, and from the impossibility of destroying the smaller mammals which might act as reservoirs Nevertheless, he considered the case sufficiently proved to justify the extension of the method on careful trial, there was no doubt of the importance of game in the disease and it ought to be controlled Game-reserves must be large and suitable, with natural boundaries, in one area there were two small reserves with an intervening settled strip, and under certain conditions of rainfall the animals trekked from one reserve to the other across the inhabited area and a large main road.

Chemotherapy

There was no doubt, said Dr. Andrews, that emetine was the best drug for *T congolense* and Bayer 205 for surra in equine animals Edwards had used the method of intrathecal inoculation, and found that the dosage must be regulated in accordance with the amount of tissue which could be reached by the drug and the amount of dilution which would be expected in such a direct method There was difference of opinion as to whether the aim should be complete sterilisation or the checking of the disease until the natural defences were built up and the patient became tolerant Chemotherapy could assist prophylaxis by keeping an area clear during threatened periods

Dr P Manson-Bahr said that there were two features in the introduction of any new drug which the practitioner of tropical medicine soon learned to realise—that the action of a drug on the parasites of an artificially injected animal did not necessarily correspond with its therapeutic effects in man and that there was an infinite variety in the reaction of individual patients to specific remedies

Bayer 205 or Germanin, said Dr Manson-Bahr, was a white flocculent powder which appeared to be much more effective when injected intravenously than when given orally or intramuscularly The dose for an adult man was assessed, after trial, at 10 g for permanent cure, given in 1 g doses weekly A single injection caused a disappearance of all the trypanosomes from the blood stream in about 18 hours after a remarkable momentary proliferation Relapses after 5 g were not infrequent, and a strain of Bayer 205 fast trypanosomes might be evolved in man, as in mice, monkeys, and cattle Unfortunately, the drug was a renal irritant and produced a subacute nephritis with albumin and casts, which might persist for six weeks after treatment had stopped Occasionally an acute fatal nephritis had supervened It did not influence the meningeal reaction, so that patients in the second stage of the disease inevitably relapsed The intrathecal method of administration was highly dangerous Modern German workers thought that intensive treatment during the first week (2 to 3 g in two to three days) ensured permanent sterilisation and diminished the liability to so-called fastness There was some evidence that Bayer 205 was better for infections with *T rhodesiense* than with *T gambiense* In his own opinion it was the drug of election for early hæmic infections and for those cases in which the trypanosomes had become fast to arsenical or antimonial preparations

Tryparsamide, he continued, cleared the blood in infections with *T gambiense* in from 6 to 12 hours when given in doses of 1 to 5 g. intravenously The only untoward symptom was dimness of vision Subcutaneous injections produced abscesses The drug had a profound influence on the meningeal reaction and was, therefore, the drug of election in the second and third stages of the disease Whether or not the drug entered the cerebro-spinal fluid, the cell-count and albumin-content were greatly influenced and clinical improvement proceeded pari passu Failures with the drug were most likely to occur in patients whose trypanosomes had been rendered arsenic-fast by previous treatment with atoxyl and soamin The present outlook in treatment was most hopeful, great advances had been made during the last six years There was a close analogy between trypanosomiasis and syphilis In both a massive invasion of the nervous system took place in the terminal stages only, tryparsamide had proved effective in cerebral syphilis as well as in cerebral trypanosomiasis The most effective and rapid treatment of human trypanosomiasis lay probably in the combination or alternation of Bayer 205 and tryparsamide Since the two drugs were the antithesis of each other, no fastness could develop by alternation Brevity in treatment was of the first importance in dealing with Central African natives who would not remain in hospital

Discussion

Dr J **Gordon-Thomson** said that morphologically the trypanosomes of animals and man showed no differences. An organism indistinguishable from *T gambiense* could be isolated from wild antelopes In 1921 Duke had put forward the hypothesis that certain trypanosomes had possibly become monomorphic through long mechanical transmission, some observations recently made in the School of Tropical Medicine tended to confirm this It was quite possible to produce from *T gambiense* and *T brucei*, by transmission through rats, a strain which to all intents and purposes was indistinguishable from *T evansi* Thompson and Robertson had recently shown that after repeated subinoculation a species lost its characteristic morphology, but if the host were suddenly changed the original characteristics sometimes reappeared A dose of an arsenical preparation might act in the same way as a change of host, altering a strain which had been monomorphic in rats for several years into a polymorphic variety It was very difficult to inject *T gambiense* into the rat, two rats had been successfully inoculated from a human case, but showed very little for six months, save a few trypanosomes in the blood The virulence increased up to a certain point by subinoculation, in one rat it had actually decreased It was possible to cure a rat clinically by tryparsamide, for instance but enough trypanosomes to kill a normal rat in a fortnight remained in the cerebro-spinal fluid and were still found there after the rat had been healthy for weeks and had reared a healthy family

Dr **Humphrey Neame** showed photographs of sections of the eye of a dog which had a marked corneal opacity Keratitis had been produced in many experimental animals—dogs, goats, and a horse —by trypanosome infection The sections showed an increase of cells in the periphery of the cornea which was partly necrosed, and there was a mass of fibrous material, containing many trypanosomes, in the anterior chamber Interstitial keratitis and iridocyclitis had been reported in men suffering from trypanosomiasis The condition was comparable with the keratitis of canine distemper and of syphilis, with the periodic ophthalmia of horses, and with tuberculous and leprous keratitis in man and cats It was a local manifestation of a blood infection and was of considerable clinical importance

Colonel F **Harvey** said that when he was working with Sir David Bruce in Uganda and Nyasaland they had found that they were dealing with three trypanosomes—a small *congolense* type, a larger *vivax*, and the *T brucei*, which was polymorphic in the original slides The *T brucei* monomorphic strain was slightly different from the local Nyasaland strain and contained more stumpy forms The strain originally sent home had been found in a few cases at this time, it was monomorphic and produced a very chronic illness in dogs, whereas the ordinary *T brucei* killed them very rapidly The explanation of the monomorphic trypanosome described first as *T brucei* might be that it was this strain which reached home, as it would have been impossible to get a dog home alive if it had been infected with the polymorphic strain A trypanosome found in the wart-hog was very virulent for animals, especially the pig and the monkey, but in goats it produced a very chronic illness Subinoculation from the goat to the monkey was very difficult, but when achieved was found to produce a very chronic illness in the monkey Attempts had been made to pass the monomorphic strain through the fly to change it back, but it was very hard to get the flies to pick up the infection, and when they fed again on dogs it was found that no alteration whatever had been produced in the trypanosome

Sir **John Moore** spoke of the successful results of treatment in India by potassium and sodium antimony tartrates That country was faced with a serious epidemic of surra in horses, and camels were being decimated by this disease The use of Bayer 205 had given excellent results

LONDON ASSOCIATION OF MEDICAL WOMEN'S FEDERATION

A MEETING of this Society was held on Dec 14th, Miss E **Bolton**, the President, being in the chair

Dr **Harrington Sainsbury** read a paper on the

Problem of Resuscitation after Systemic Death

He said that systemic death, while putting an end to the corporate life of the body, viewed as a collection of *associated* organs and tissues does not terminate somatic life—i e, the life of the body viewed as a collection of *dissociated* organs and tissues At the moment of systemic death these organs and tissues retain more or less of individual life and have their several rates of dying, though the tenure of life is not of long duration even for the most hardy of them Since the blood serves as a carrier of elements indispensable to the tissues, its coagulation-point is a crucial factor in the determination of the possibility of resuscitation While the blood remains fluid systemic life may be regarded as capable of resuscitation, given the persistence of a sufficiency of somatic life in the tissues generally and in the heart specially.

As a practical problem, the question of resuscitation will scarcely arise in the case of death at the natural term of life where the vital powers have for a long while been manifestly ebbing, in spite of the use of such stimulant means as we possess in diet and appropriate medicinal measures Neither will it arise in the case of long drawn-out and exhausting diseases, such as tuberculosis and cancer, where all the evidence indicates that at best there can only be a temporary rally The likelihood, however, of a recovery of the powers of the mind and body, which, though brief, might yet suffice to permit of some all-important act say, for testamentary purposes, might have to be considered, but such cases would be rare On the other hand, the problem becomes eminently practical in proportion as it appears that the inherent powers of the tissues, severally, are unexhausted and that the systemic death present is rather of the nature of a suspended animation which has arisen more or less abruptly at the heart or at the lungs In such cases the somatic vitalities being still in their plenitude, there is no reason why, if the heart and the respiratory apparatus can be restarted, life should not proceed to its usual term At the threshold of life this problem arises in the case of the stillborn infant, in whom the indications point either to an arrested heart or unstarted breathing, and, again and again, in the average course of life this same problem is liable to confront the doctor, whether through the incidence of mishap or of acute disease, or in the midst of an operation, at times of the most trivial kind, or, it may be, even during the administration of an anæsthetic before the operation has begun

Dr Sainsbury pointed out that the enormous disparity between the forces engaged in the respiratory and in the circulatory functions made resuscitation of the latter system a task of far greater magnitude For, though the first breaths taken after birth had to overcome a very considerable inertia of the respiratory apparatus, respiration once established, the muscular effort required to keep it going in normal breathing was no more than that needed to move the volume of tidal air in and out of the chest In the absence of obstruction to the air-passages, restarting of arrested respiratory motion was comparable to the slight touch which starts the pendulum of a clock already wound up, and it was a well-recognised measure which had passed beyond the need of discussion On the other hand, when the circulation of the blood had failed a force had to be supplied to meet a great resistance—namely, a pressure corresponding in man to approximately 150 mm of mercury in the aorta Fortunately, it was not necessary that the full momentum of the circulation should be generated all at once The elasticity of the arterial system and the mechanism of the aortic

ROYAL SOCIETY OF MEDICINE

SECTIONS OF COMPARATIVE MEDICINE AND TROPICAL DISEASES AND PARASITOLOGY.

A COMBINED meeting of these Sections was held on Jan 5th, SIR D'ARCY POWER, President of the Section of Comparative Medicine, in the chair.

DR W H ANDREWS opened a discussion on

TRYPANOSOMIASIS IN MAN AND ANIMALS

He spoke of the simplicity of early classifications and the maddening complexity which had followed He regarded the recent tendency to group and simplify, particularly the work of Wenyon, as a sign of progress Classification was very difficult and was impossible on morphological grounds alone, but the introduction of biological characters into the scheme of classification was very unsafe The mode of development in the fly appeared to be stable, but such characteristics as virulence to particular species were of very doubtful value Even the morphology was not absolutely fixed. There was constant difficulty in trying to see order amidst the chaotic masses of facts It was doubtful whether the effects of artificial propagation from mammal to mammal were the same as those of mechanical transmission in the field The speculation was fascinating but many facts seemed to argue against it The *T brucei* as originally described by Plimmer and Bradford was now unknown. Probably the organism was polymorphic and had taken on that particular monomorphic form as a result of repeated inoculation in the laboratory The whole question of virulence was one on which much more information was needed In many cases cattle harboured trypanosomes without suffering any harm and formed reservoirs, yet at times there would be serious outbreaks of disease among them from the same organism In some cases age appeared to be a factor as well as the strains of host and organism The effect of the mammalian host on the parasite might be very considerable There was no direct evidence of such an effect on trypanosomes, but the ultramicroscopic virus of African horse-sickness, for example, might be found on recovery from inoculated animals to have undergone sudden increase in virulence or to be much weaker Continued observations were needed on the difference between mechanical and cyclical transmission and their effects on virulence Parties of men and animals were constantly going up from Natal to Zululand, they lost dogs and horses, and many animals still harbouring the parasite must return with them, yet trypanosomiasis was never brought down to Natal The only case of naturally occurring *T gama* infection the speaker knew of was in a laboratory dog which had eaten the carcasses of artificially infected guinea-pigs If the work of Cross and Patel could be confirmed, it would be recognised as one of the most important pieces of investigation ever done in this field

Prophylaxis

The importance of domestic animals as reservoirs must not be forgotten, continued Dr Andrews The objections to destruction of game arose from sentiment, from fear of making the organisms concentrate on man, and of scattering the game (and with it the fly) by large hunts, and from the impossibility of destroying the smaller mammals which might act as reservoirs Nevertheless, he considered the case sufficiently proved to justify the extension of the method on careful trial, there was no doubt of the importance of game in the disease and it ought to be controlled Game-reserves must be large and suitable with natural boundaries, in one area there were two small reserves with an intervening settled strip, and under certain conditions of rainfall the animals trekked from one reserve to the other across the inhabited area and a large main road

Chemotherapy

There was no doubt, said Dr Andrews, that emetine was the best drug for *T congolense* and Bayer 205 for surra in equine animals Edwards had used the method of intrathecal inoculation, and found that the dosage must be regulated in accordance with the amount of tissue which could be reached by the drug and the amount of dilution which would be expected in such a direct method There was difference of opinion as to whether the aim should be complete sterilisation or the checking of the disease until the natural defences were built up and the patient became tolerant Chemotherapy could assist prophylaxis by keeping an area clear during threatened periods

DR P MANSON-BAHR said that there were two features in the introduction of any new drug which the practitioner of tropical medicine soon learned to realise—that the action of a drug on the parasites of an artificially injected animal did not necessarily correspond with its therapeutic effects in man and that there was an infinite variety in the reaction of individual patients to specific remedies

Bayer 205 or Germanin, said Dr Manson-Bahr, was a white flocculent powder which appeared to be much more effective when injected intravenously than when given orally or intramuscularly The dose for an adult man was assessed, after trial, at 10 g for permanent cure given in 1 g doses weekly A single injection caused a disappearance of all the trypanosomes from the blood stream in about 18 hours after a remarkable momentary proliferation Relapses after 5 g were not infrequent, and a strain of Bayer 205 fast trypanosomes might be evolved in man, as in mice, monkeys and cattle Unfortunately, the drug was a renal irritant and produced a subacute nephritis with albumin and casts, which might persist for six weeks after treatment had stopped Occasionally an acute fatal nephritis had supervened It did not influence the meningeal reaction, so that patients in the second stage of the disease inevitably relapsed The intrathecal method of administration was highly dangerous Modern German workers thought that intensive treatment during the first week (2 to 3 g in two to three days) ensured permanent sterilisation and diminished the liability to so-called fastness There was some evidence that Bayer 205 was better for infections with *T rhodesiense* than with *T gambiense* In his own opinion it was the drug of election for early hæmic infections and for those cases in which the trypanosomes had become fast to arsenical or antimonial preparations

Tryparsamide, he continued, cleared the blood in infections with *T gambiense* in from 6 to 12 hours when given in doses of 1 to 5 g intravenously The only untoward symptom was dimness of vision Subcutaneous injections produced abscesses The drug had a profound influence on the meningeal reaction and was, therefore, the drug of election in the second and third stages of the disease Whether or not the drug entered the cerebro-spinal fluid, the cell-count and albumin-content were greatly influenced and clinical improvement proceeded pari passu Failures with the drug were most likely to occur in patients whose trypanosomes had been rendered arsenic-fast by previous treatment with atoxyl and soamin The present outlook in treatment was most hopeful, great advances had been made during the last six years There was a close analogy between trypanosomiasis and syphilis In both a massive invasion of the nervous system took place in the terminal stages only, tryparsamide had proved effective in cerebral syphilis as well as in cerebral trypanosomiasis The most effective and rapid treatment of human trypanosomiasis lay probably in the combination or alternation of Bayer 205 and tryparsamide Since the two drugs were the antithesis of each other, no fastness could develop by alternation Brevity in treatment was of the first importance in dealing with Central African natives who would not remain in hospital

valve enable the summation of small efforts and give the necessary time for recovery Dr Sainsbury said that the period during which the blood remained fluid and the heart-muscle retained its contractility could not be given precisely in minutes, but must vary with the individual In practice the longest recorded time between apparent systemic death and resuscitation would stand as a working precedent Certain cardiologists of the newer school had thrown doubt on the susceptibility of the heart to direct stimulation, but in his opinion this attitude of scepticism ran counter to most definite evidence

As to the most powerful means of revival, Dr Carl Bodon, of Budapest,[1] had collected from the literature the records of 90 cases in which the various recognised stimulants had been tried, and from the study of the results he placed adrenalin first on the list He gave details of the method whereby 1 c cm of a 1 in 1000 solution of this drug could be injected into the cavity of the right ventricle, this dose being suitable for an adult in middle life For the details, which are very precise as to site of puncture and length of needle and direction of its course, the original paper must be consulted

An alternative reliable method of stimulation was cardiac massage In this connexion Dr. Sainsbury quoted cases published by Mr Girling Ball Dr Glover, and Lieut -Colonel Cook Dr Glover's case recovered with heart massage alone whereas in the other two cases both adrenalin and heart massage were employed In Dr Bodon's own case adrenalin without heart massage was successful Dr Sainsbury held that the use of adrenalin should come first on the following grounds. (1) The simplicity of the procedure and its rapid applicability (In these cases the sooner our stimulants come into use the better) (2) When effective, the response would appear to be more prompt (3) The comparatively slight risk involved (4) The general disturbance—a negligible quantity

Dr. Sainsbury concluded his address with a discussion on the ethics of resuscitation Was it always a doctor's duty to re-kindle life in a patient who might not be grateful for his recall to the troubles which he had left behind? He put forward the following cases as examples: Suppose a case of pneumonia and that we happen to know of the presence of inoperable cancer, of which the patient might be unaware, should we feel justified in seeking to resuscitate, the pneumonia having proved fatal? Or suppose that in like case the first symptoms of locomotor ataxy or of G P I, or of some other serious mental disorder should have appeared, what then? Or, leaving organic disease and entering the psychic domain, suppose the presence of a great and abiding sorrow, the existence of grave anxieties, financial or other, which on no show of likelihood could be relieved, and, further, that we know that death would be welcomed—should we still feel that we must endeavour to recall that life which an intercurrent malady had extinguished? Our duty is to cure, so we may, failing this, to prolong life, upon terms, failing this, to make life more endurable, but is it a duty to thrust life upon an unwilling recipient? We are here to relieve, not to inflict burdens These objections would not arise in the case of stillbirth, where the duty to suscitate (not *re*suscitate) is unquestionable

Finally, Dr Sainsbury pointed out that in the event of sudden, unanticipated, unprepared-for death, the case for resuscitation was overwhelmingly strong Therefore, in every hospital, in every nursing-home, and in the emergency equipment of every medical practitioner, the apparatus for intracardiac injection, together with the remedy, should be kept in readiness Adrenalin should not, however, be kept in reserve until life has departed, but in every case of heart failure, which was ceasing to respond to hypodermic or intravenous injections, intracardiac injections should be tried in order to forestall death, if possible

Discussion

Lady **Briscoe**, from her work on experimental animals, endorsed what Dr Sainsbury had said about the ease of restarting respiratory movement and the difficulty of restarting the heart She had never found cardiac massage of much help In cats accidentally killed from an overdose of chloroform, she had noticed that the diaphragm was not excitable after death, though other muscles remained excitable Was it possible that deaths from chloroform were due to direct poisoning of the respiratory muscles?

Dr **Letitia Fairfield** suggested that it was dangerous to speculate as to the ethics of resuscitation, a newly-born infant might be resuscitated to a life of many troubles, yet no one would question the doctor's duty. She proposed a vote of thanks to Dr Sainsbury, which was seconded by Dr **Hazel Gregory**, and carried with applause

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND

A MEETING of this Society was held at the London School of Medicine for Women on Jan 7th and 8th, Prof J H **Dible** in the chair

Agnes R Macgregor (Edinburgh) demonstrated a series of sections through the whole lungs of infants, prepared by Mr Hamilton in the laboratory of the Royal College of Physicians, and illustrating the pathology of broncho-pneumonia She emphasised the importance of lymphangitis in extending and continuing the infection —S L **Cummins** (Cardiff) showed that coal-mining might be a dangerous occupation to a man who had previously worked in hard silica rock because coal dust accumulated to an intense degree in the silicotic lung —C G **Pope** (London) found that phenol destroys antitoxin faster than toxin, so that if the concentration of preservative phenol is raised to an effective level by freezing, a toxin-antitoxin mixture may become toxic.—J W S **Blacklock** (Glasgow) described five cases of Gaucher's disease at ages from 18 months to 38 years, and discussed the changes in the spleen, liver glands, and bone-marrow Two cases occurred in one family The condition could be diagnosed by puncture of the spleen He also pointed out that tubercle bacilli could sometimes be obtained from tissues by culture when guinea-pig inoculation gave negative results —F B **Smith** and S **Miller** (Harrogate) described an epidemic of fowl-typhoid in Yorkshire in which *Bacillus sanguinarium* was isolated, the disease affected only birds a year old or younger They also gave an account of their successful experience in the control of measles in families by injecting serum from a measles convalescent at such a time after infection that a mild but immunising attack of the disease followed, and showed specimens from a doubtful case of Hodgkin's disease —G **Hadfield** (Bristol) showed an example of primary pulmonary arterio-sclerosis and differentiated the condition from the cases due to mitral stenosis, pulmonary fibrosis, and syphilitic arteritis Intense cyanosis with polycythæmia is a constant and remarkable symptom.—J B **Duguid** (Manchester) presented statistics showing the steadily progressive increase in the prevalence of carcinoma of the lung at the Manchester Royal Infirmary during the past 50 years Males are affected much more frequently than females and an excessive proportion of the cases are by occupation drivers of road vehicles —A L **Taylor** (Leeds) gave the results of a systematic survey of the heterotopias of the alimentary tract Of the congenital group, superficial abnormalities are commonest as gastric glands in the œsophagus and intestinal mucous membrane in the stomach (found in 26 per cent of excised stomachs), the deeper series comprise adenomyoma of the stomach and aberrant bits of pancreas The acquired group arise mostly during regeneration and the repair of injuries however, of the bad keeping properties of the solution, which loses three-fourths of its strength in the course of a week

It will be a convenience to many orthopædic surgeons to have these interesting papers collected into one volume

PLASTIC SURGERY OF THE KNEE-JOINT

L'Arthroplastie du Genou By CHARLES-HENRI CHEVALLIER, Aide d'Anatomie à la Faculté de Médecine, Ancien Interne des Hopitaux de Paris Paris Masson et Cie 1926 With seven plates Pp 152 2*s*

UNTIL the last 20 years most surgeons who had to deal with serious disease of the knee-joint were well content if they could leave the patient with a stiff, straight or nearly straight limb Murphy, of Chicago, was one of the first to substitute a movable joint for ankylosis in 1901 Hoffa, Payr, and Putti, of Bologna, afterwards perfected the operation until the last-named is able to claim 84 per cent of successes in the 63 cases reported by him Dr Chevallier has now published a useful monograph in which he records the history of attempts at forming a new knee-joint, and shows by a study of experiments on animals, and of the pathology of false joints after fracture in what direction success was to be looked for The commonest cause of non-union of fractured bones appears to be the intervention or interposition of soft parts between the fragments Success in the formation of new joints in ankylosed limbs has been reached mainly by very carefully and completely covering the remodelled bone-ends with an enduring animal membrane, and for this purpose the fascia lata of the patient's own thigh has been found to be the best Strips the width of the joint, and as much as 40 cm long, have thus been transplanted, without producing muscular hernia or any permanent damage to the limbs from which they have been taken The operation may now be considered as well established, but not a routine one, nor one to be lightly undertaken An efficient musculature is essential to functional success and this operation shows once more how far more important muscles are than ligaments to the stability of a joint The strength of will and determination of the patient must play a large part in producing a good functional result after the most perfect technique in operation Without this power of the patient to forgo present ease for future benefit the art of the surgeon is unavailing

All these and other considerations are well set before his readers by Dr Chevallier, whose book concludes with a detailed description of that modification of Putti's operation which he recommends, illustrated by excellently clear plates We recommend a study of this monograph to any surgeon who is thinking of mobilising an ankylosed knee-joint

PAIN

Körperschmerzen (mit Ausnahme der Bauchschmerzen) Third edition By Prof Dr NORBERT ORTNER, Principal of the 2nd Medical Clinic at Vienna University Berlin and Vienna Urban and Schwarzenberg 1925 Pp 426 M 18

SOME years ago Prof Ortner published a treatise on abdominal pain as the first half of the first volume of a text-book entitled "Klinische Symptomatologie innerer Krankheiten" In 1919 appeared the first edition of the work under review, which is a comprehensive survey of the clinical significance of localised pain, other than abdominal, and has proved so popular that it has now reached its third edition Those who read German should find it a most useful reference book, for it is arranged in sections corresponding to different parts of the body, and deals in detail with the different ailments that different degrees and kinds of pain may denote It is in a book of this kind that the German method of patient and laborious classification is at its happiest The close attention to minute detail that makes an essay unreadable is the soul of an encyclopædia to which one turns for a specific item of information Prof Ortner is not concerned with the nature of pain, but purely with its value as a guide to diagnosis We can recall no book in English in which a physician can turn up a section on heart pain, for instance, find the disease he suspects in a marginal note, and read of exactly the variety of pain that is usually associated with that ailment, such a quickly accessible check to diagnosis should be a valuable possession to both the clinician and the general practitioner Were the book in English, it would probably attract a considerable demand, and it may be hoped that the publishers will arrange for a translation

MODERN TREATMENT OF HÆMORRHOIDS

By JOSEPH FRANKLIN MONTAGUE, M D, F A C S, of the Rectal Clinic, University and Bellevue Hospital Medical College London and New York J B Lippincott Company 1926 Pp 206 21*s*

THIS is a practical and up-to-date exposition For the most part the views which the author expresses and seeks to popularise among the medical profession in America represent the current practice in this country The work of St Mark's Hospital, London, is referred to in particular and is cited in most instances in corroboration of the author's statements One unfortunate error in this connexion is apparent On pp 150 and 256, in criticising the clamp and cautery operation as regards post-operative pain, Dr Montague quotes, inaccurately, from the figures collected by the late H Graeme Anderson In Mr Anderson's original paper the clamp and cautery operation and the ligature method were stated to have resulted in severe pain in 0 per cent and 10 per cent respectively Dr Montague records these figures as 70 per cent and 33 per cent

The treatment of piles by operation, injection, radium and electrotherapeutic methods are described clearly and adequately, with the indications for the different methods The author prefers for the injection treatment of internal hæmorrhoids a 10 per cent solution of cresylic or carbolic acids to the quinine-urea which seems to be the favourite of most American proctologists Treatment by burying radium emanation seeds into the piles has given promising results in the way of fibrosis, and a further series will be reported on later Complications and sequelæ likely to arise from the different procedures are discussed The author appears to be more apprehensive of hæmorrhage after the clamp and cautery operation than our experience suggests, he advocates the insertion of a mattress suture of catgut into the stump before removing the clamp

The print is large and clear, and the illustrations are satisfactory

PSYCHOLOGY AND ETHNOLOGY

By W. H R RIVERS London Kegan Paul, Trench, Trubner and Co 1926 Pp 324 15*s*

THE "International Library of Psychology, Philosophy, and Scientific Method," appearing under the general editorship of Mr C K Ogden, of Magdalene College, Cambridge, of which the first 50 volumes are announced, is a tremendous undertaking When it is complete it will form not a systematic treatise *de omnibus rebus et quibusdam aliis*, but a collection of monographs on such topics—and they are many—which may come under its title The present volume is a collection of 21 essays, published and unpublished, by the late Dr Rivers, and it will be read with the same feelings of confidence and charm which his other writings have brought They are exceptionally characteristic, for they exhibit parts of his pilgrimage through medicine and psychology to the realisation that the essentials of anthropology—of which at one time he took little account—are at bottom psychological And it is this intimate admission to the progress of a mind so keen and unprejudiced that makes the book especially worth reading As far

Reviews and Notices of Books.

NASAL ACCESSORY SINUSES

Pathology and Treatment of the Inflammatory Diseases of the Nasal Accessory Sinuses Fifth edition By Prof Dr M HAJEK, Chief of the Laryngo-Rhino-Otological Clinic, University of Vienna Translated and edited by JOSEPH D HEITGER, A B, M D, Louisville, Kentucky, and FRENCH K HANSEL, M D, M S, St Louis, Missouri London Henry Kimpton 1926 Two vols Pp 294 and 408 75s

IT is well that this work has been made accessible in an English translation, for Dr Hajek has been a pioneer in the rapid advance of our knowledge of disease of the nasal accessory sinuses, and is to-day one of the leading authorities on the subject The translation is good, and only rarely has too close an adherence to the German idiom rendered the phraseology a little obscure The first edition in German was published in 1898, and, as the translators say, it placed the pathology and therapeutics of suppurative affections of the nasal accessory sinuses for the first time on a solid foundation The work presents an authoritative account of the anatomy, pathology, and treatment of these diseases, it is well written and arranged, and is as complete as a book on a subject of such variety can well be expected to be A few methods of treatment in general use here are omitted, among which is Dr Watson Williams's method of opening the frontal sinus intranasally The first 159 pages are occupied by general considerations, a clear description of the detailed anatomy of the regions concerned is first given, and is followed by chapters on pathogenesis, symptomatology and diagnosis, the latter including a short but good account of radiographic methods The remainder of the first volume, and the greater part of the second, is taken up by the description of inflammatory diseases of the individual sinuses and their treatment The methods advocated are eminently sane and are mostly those in general use, largely because Dr Hajek has himself done much to standardise them We note that he states that the Caldwell-Luc operation on the maxillary antrum may be performed, under local anæsthesia, in the out-patient department, and that hospital confinement is unnecessary Chapters on combined affections of the sinuses and on complications involving the eye and orbit and the brain and cranial cavity are useful There is an appendix on affections of the sinuses associated with ozæna, Dr Hajek denies that he is a keen supporter of the theory that ozæna is caused by accessory sinus infection; he confines himself here to a demonstration that in ozæna there are often areas of localised secretion, and to the analysis of cases in which the localised secretion was found in accessory sinuses and elsewhere

The volumes are beautifully produced, good illustrations being plentiful, there is a useful index and a very full list of references to literature, which occupies 33 pages The English translation is a noteworthy addition to rhinological literature

SCOLIOSIS

Rotary Lateral Curvature of the Spine By SAMUEL KLEINBERG, M D, F A C S, Assistant Surgeon, New York Hospital for Ruptured and Crippled, Member of the American Orthopædic Association New York Paul B Hoeber, Inc London Humphrey Milford, 1926 Pp 311 30s

READERS of works on scoliosis will turn their attention first to what the author has to offer under the head of prognosis Dr Kleinberg tells us that "the very mild cases of rigid scoliosis can be satisfactorily treated and often cured by gymnastic exercises of one type or another" In our experience, however, no *rigid scoliosis* can be properly called "very mild," few cases can be improved, and fewer cured The author adds "The moderate types of scoliosis can be markedly improved in more than 60 per cent of the cases They can practically always be arrested . The severe types of cases can be somewhat improved and may be prevented from becoming worse" These views appear to us decidedly optimistic Too many of such cases run their course, despite all that can be done by surgeons, instrument-makers, and physiotherapeutists

Dr Kleinberg describes the normal anatomy of the spinal column, the classification and pathology of the various types of scoliosis, and the methods of treatment which have given him satisfaction. The gymnastic exercises described are likely to be of use in cases of weak spines with what the author calls functional deformity—i e, a slight habitual curve which can be corrected by the patient or the masseuse Forcible correction is described and discussed, as well as the fixation method introduced by Hibbs, the object of which is to ankylose the vertebræ through their spinous processes by means of bone grafts such as were introduced by Albee for treatment of Pott's disease In place of cumbrous plaster jackets Dr Kleinberg uses a steel brace of his own devising The book is well printed and well illustrated with 140 figures

AFFECTIONS OF THE VERTEBRAL COLUMN

Études sur les Affections de la Colonne Vertébrale By Dr ANDRÉ LÉRI, Professeur Agrégé à la Faculté de Médecine de Paris, Médecin de l'Hôpital de la Charité Paris Masson et Cie 1926 Pp 526 7s. 6d

THIS book of over 500 pages and 115 figures consists of a collection of papers—possibly with additions—which have been contributed by the author to the medical societies and the medical press of Paris The name of Dr Pierre Marie, who has contributed a preface, is closely associated with the disease known in this country as spondylitis deformans and by various cognomens, and Prof Léri is an enthusiastic advocate of the rheumatic ætiology of this, as of various other affections of the vertebral column, and of the muscles of the trunk and shoulder girdle The first section of the book, on anomalies and disorders of development, contains some interesting records of cases of trophic œdema and incontinence of urine which are attributed to spina bifida occulta. An operation designed to free the cord or the nerves of the cauda from constriction by bands of fibrous tissue is described, and good results are claimed for it Other sections on defective development of the bones resulting in sacralisation of lumbar vertebræ, numerical defect of vertebræ, defects of the sacrum, and their results are worth study Throughout the book the importance of radiographic evidence is rightly insisted upon. The evidence offered of the traumatic nature of the affections described in the second section is, in our opinion, insufficient The gradual ossification of ligaments and the slowly progressive palsies which are attributed to compression are not generally recognised as the result of long previous injury The third section on ankylosing affections of the spine and the following one on localised forms of vertebral rheumatism deal with matter unfamiliar to many British readers In this country we should require stronger evidence of pressure on the spinal nerves than is brought forward by Prof Léri before admitting that such disabilities as palsy and atrophy of isolated muscles or groups of muscles of the shoulder, neck, &c, are due to rheumatic affection of the bones and ligaments of the vertebral column The writer claims to have got good results in cases of stiff spine attributed to rheumatism by the injection of thorium X In such a crippling and generally hopeless condition as spondylitis deformans even desperate remedies might be tried, and it may be as well to put on record here that Prof Léri uses it in the form of bromide of thorium X in a physiological serum, injected every week subcutaneously or intramuscularly in doses of 100 to 300 microgrammes He warns his readers,

NDON: SATURDAY, JANUARY 15, 1927.

PULMONARY EMBOLISM

LMONARY embolism is one of the most artening accidents which may happen after an ation No surgeon can foretell far less forestall ccurrence. for the underlying causal pathology most completely unknown Dr W. A Lister here in this issue contributes a statistical study amples which have occurred in the practice of London Hospital He is able to draw certain usions Briefly his figures seem to prove that olism is dependent upon three factors age post-ative muscular immobility which allows of venous ation, and interference with diaphragmatic ration. by which the suction effect of inspiration the large abdominal veins is lessened Thus olism is uncommon after such a large dissection adical removal of the breast for carcinoma, and operations upon the bladder. rectum or female al organs it is almost confined to those cases e an abdominal incision has been made This ingly confirms the experience at the Mayo Clinic vaginal and abdominal hysterectomy where the facts were noted Dr Lister does not record instance of embolism after nephrectomy. such no doubt do occur though they would seem to ery uncommon If interference with diaphrag-c respiration is such an important factor in the ence of pulmonary embolism it should, one would occur more commonly after operations upon upper abdomen than after those upon the pelvic s. But this does not appear to be so with any ancy, for although the proportional incidence mbolism after duodenal and gastric operations 7 per cent. and after gynæcological operations er cent. it rises after operations upon the bladder. ra, and prostate to 16 8 per cent, which seems than can be accounted for by the higher average f the urological patients (56 years) compared with upper abdominal patients (44 years). One very rtant and unexpected conclusion is the absence y evidence for regarding sepsis as playing a part e incidence of pulmonary embolism This is iently surprising and there are numerous other omena connected with this serious complication h are equally interesting and inexplicable We ot know why the clot should originate so often e left iliac vein or why it does not occur equally only on the other side Often enough we cannot find the site of origin when it is reasonable to e that a minute clot, leaving no trace on the f the vein, has been held up in the cavities of the amongst the chordæ tendineæ, or in the auricular ndage. until it has reached a large size before dislodged again into the circulation Two however, emerge from Dr Lister's study, it seem to be right to encourage free movements e limbs and to insist upon breathing exercises every abdominal intervention.

ere is another aspect of Dr Lister's paper to attention should be called, the paper is an in-tive example of a method of research which is beginning to be appreciated at its true value. ugh in these days there is no want of candidates for grants and appointments to research. there is undoubtedly a too widespread impression that no investigation is worthy of that name unless it involves the use of complicated technique and is pursued amid thousands of pounds' worth of apparatus Many young men—and some older ones—are in need of the rebuke addressed to Peter "What God hath cleansed, that call not thou common The truth is that in such institutes of pathology as Prof H M. Turnbull's department at the London Hospital there are accumulating records the analysis of which would throw light upon many obscure places Since such analyses involve the use of statistical methods it is sometimes suggested that they should be handed over to professional statisticians This proposal we believe to be wholly unsound It is probable that an investigator who is not a professional statistician will sometimes make even serious mistakes in the choice and application of a method, but it is certain that the professional statistician not intimately acquainted with the material he is using and the subject he proposes to investigate will run still more serious risks At worst the amateur statistician will over-estimate the value of his conclusions and if he fairly puts his cards on the table others may judge for themselves The statistician not familiar with the subject matter will not know what cards *ought* to be put on the table Dr Lister has both clearly presented and sufficiently analysed his data His conclusions seem well supported by evidence. the strength and inherent weaknesses of which are clearly described The reports by Dr. Janet Lane-Claypon, which the Ministry of Health has published during the last few years. illustrate the application of a like method to clinical statistics These reports and Dr. Lister's differ in two ways from the similar papers which are often written as theses for university degrees The statistical treatment. without pretending to be more than elementary is at least much superior to what has long done duty for statistical analysis in medical papers The scope of the data is immensely wider. That is perhaps the crux So long as an analysis of *m* consecutive cases of such or such a disease is treated as a matter for a few hours examination of documents and a few evenings' writing. this kind of research is rightly despised The tackling of data on the scale of Dr Lister or a fortiori, of Dr Lane-Claypon is quite another thing and requires much time and patience We hope that when the London School of Hygiene opens its teaching department of epidemiology and vital statistics (over which Prof Major Greenwood is to preside) it will gather as its research students not only public health men (in the strict sense) but also young pathologists, surgeons, and physicians resolved to work in the field which Dr Lane-Claypon and Dr Lister show to be fruitful. It is regrettable that many hospital records are still badly compiled; it is even more regrettable that the good records are so little utilised.

DROPLET INFECTION AND CARRIERS

The little drops of water have, it seems triumphed over the little grains of dust in current teaching regarding the source of infection in bacterial disease. It is nearly 40 years since Flügge insisted that it was the shower of sputum droplets rather than the wafting of dried bacilli, championed by Fränkel, which constituted the chief danger of contracting tuberculosis, and although in this disease the as they may be classified, three of the papers are medical about five are psychological, and ten deal with the evidence which may be derived from habits and customs that early human communities were much less isolated than is often supposed The papers were prepared for the press by Mr H J Massingham and they are edited by Prof G Elliot Smith, who contributes a graceful introduction, tinged with some glee at Dr Rivers's conversion to "diffusionist" views

PUBLISHED PAPERS 1925–26

By Members of the Staff of the Middlesex Hospital Medical School, London

A PORTION of the year's clinical and research work at the Middlesex Hospital is represented by the 27 reprints here collected into one volume They fall naturally into certain groups which serve as an indication of the trend of modern scientific medicine On the biochemical side Prof E C Dodds reports various important advances In a paper with Prof Swale Vincent and Dr F Dickens he describes the production of insulin from the pancreas of teleostean fishes, with Dr Dickens and Dr S Wright he discusses the preparation and standardisation of the ovarian hormone, and he carries the investigation into the ætiology of dental caries a stage further by an account of the chemical composition of the saliva Prof J McIntosh, Mr Warwick James, and Dr P Lazarus-Barlow deal with other aspects of the same investigation in another paper In connexion with radiology, Mr Sampson Handley describes the use of radium in certain aspects of surgery Dr J H D Webster, Dr J. P Thierens, and Dr F G Nicholas report the results of the treatment of operable cancer of the breast with radiation in 15 cases, and a valuable paper on the organisation of a hospital radium service is included by Prof S Russ and Mrs R H Somerset On the clinical side various cases are recorded Dr H G Estcourt gives a good account of Gradenigo's syndrome and Dr A Moncrieff reviews the recent literature on tuberculosis in childhood Prof Swale Vincent's contributions to endocrinology are represented in three papers, two of which are devoted to the uses and abuses of endocrine therapy Such a valuable collection of papers would seem worthy of better production than that of a bound volume of variously shaped reprints

THEORETICAL BIOLOGY

By J VON UEXKÜLL London Kegan Paul, Trench, Trubner and Co 1926 Pp 362 18*s*

A MATERIALISTIC view of the universe has one great advantage over a mystical interpretation—it is easier to state and much easier to understand This book is described as an attempt to extend the doctrines of Kant's philosophy into the realm of biological thought, it is certainly not materialistic, and it is difficult to make out exactly what the author means He appears to argue that the physicist's world is meaningless and without purpose, and that the distinctive feature of the live world is that it is arranged in conformity with plan He deplores the overwhelming influence of Darwinism—which with greater respect might be written darwinism—because it has made us overlook the meaning of live things, and has left nothing but mechanical and chemical processes which proceed in their unwitting way There is probably much of interest to be quarried from the book The author's imagery of live things consisting of an essential framework of function in which a variable structure is arranged—his reminder of Roux's great saying that the goal is more certain than the route—his summary of the relation of structure and function in the statement that within its limitations each organism is absolutely perfect, there is much food here for reflection But his arguments (or possibly his translator's version of them) could surely have been put forward more intelligibly

VENEREAL DISEASES

The Diagnosis and Treatment of Venereal Diseases in General Practice Third edition By L W HARRISON, D S O, M B, F R C P Edin, Director of Venereal Department, St Thomas's Hospital London Oxford University Press 1926 Pp 558 25*s*

THE third edition of Colonel Harrison's book has been increased in size, though some of the sections of the earlier editions have been skilfully condensed It follows that valuable new material has been added The book is comprehensive and readable while being free from dogmatism. It is full of practical information as regards the straightforward treatment of venereal diseases, and advice is added as to the best method of dealing with the various complications which may arise during arsenobenzol or bismuth therapy As the volume is designed for the practitioner, it would probably have been advisable to include the names of a few bismuth preparations and their percentage bismuth-content The expert has his own favourite preparations, but the practitioner desirous of giving a course of bismuth injections would doubtless welcome guidance The communication from a member of Colonel Harrison's staff at St Thomas's Hospital V D Clinic, which appears in this issue of THE LANCET (p 148), is timely in this connexion A most valuable chapter on the medico-legal aspect of venereal diseases is added by Dr F G Crookshank The latest approved serum tests for syphilis (Sachs-Georgi, Sigma, and Kahn) are described in appendices where also some newer arsenical preparations of value in special forms of syphilis are mentioned Treatment of gonorrhœa by protein shock and the place of diathermy as an aid to treatment are referred to A general account of the methods of treatment of syphilis and gonorrhœa used in St Thomas's Hospital V D Clinic is included for the first time

This work should be in the library of every modern practitioner

HIGH BLOOD PRESSURE

Second edition Revised and enlarged By J F HALLS DALLY, M A, M D, B Ch Camb, M R C P Lond, Physician to the Mount Vernon Hospital for Tuberculosis and Diseases of the Heart and Lungs London William Heinemann (Medical Books), Ltd 1926 Pp 196 12*s* 6*d*

THIS book has undergone thorough revision and by incorporation of the most recent work has become larger by some 40 pages A notable addition is an appendix on the Treatment of Arterial Pressure by Baths and Waters, contributed by Dr R Fortescue Fox In view of the doubtful meaning and loose employment of such terms as hyperpiesis, hyperpiesia and hypertonia Dr Halls Dally has tried to clarify their relations by a new classification based on fundamental physical laws, the result is a valuable chapter, albeit one which requires close reading Considering that the study of high blood pressure is comparatively recent and views on it are therefore constantly liable to modification, the book is clearly written, though perhaps there is too much detail The importance of the diastolic pressure in diagnosis and prognosis is well set out, whilst the necessity for regarding at all times the whole pressure picture, rather than a single phase of it, receives due emphasis Especially good are the chapters devoted to treatment, to problems connected with life insurance, and to the value, little recognised, of blood pressure readings in pulmonary tuberculosis Indeed, there is little to which exception can be taken, though the statement (on p 101) that urea is harmless will probably require modification in future editions

To sum up, this is a useful summary of our knowledge on a subject of ever-increasing importance Whilst written primarily for practitioners it contains much—e g, an excellent bibliography—which will appeal to those who follow the narrower paths of medical specialisation

PULMONARY EMBOLISM

LMONARY embolism is one of the most artening accidents which may happen after an ition No surgeon can foretell, far less forestall ccurrence, for the underlying causal pathology most completely unknown Dr W A Lister here in this issue contributes a statistical study amples which have occurred in the practice of London Hospital He is able to draw certain usions Briefly his figures seem to prove that olism is dependent upon three factors age, post-ative muscular immobility which allows of venous iation, and interference with diaphragmatic ration, by which the suction effect of inspiration the large abdominal veins is lessened Thus olism is uncommon after such a large dissection idical removal of the breast for carcinoma, and operations upon the bladder, rectum, or female al organs it is almost confined to those cases e an abdominal incision has been made This ingly confirms the experience at the Mayo Clinic vaginal and abdominal hysterectomy where the facts were noted Dr Lister does not record instance of embolism after nephrectomy, such no doubt do occur though they would seem to ery uncommon If interference with diaphrag-c respiration is such an important factor in the ence of pulmonary embolism, it should, one would , occur more commonly after operations upon ipper abdomen than after those upon the pelvic is *But this does not* appear to be so with any ancy, for although the proportional incidence nbolism after duodenal and gastric operations 7 per cent, and after gynæcological operations er cent, it rises after operations upon the bladder, ira, and prostate to 16 8 per cent, which seems than can be accounted for by the higher average f the urological patients (56 years) compared with ipper abdominal patients (44 years) One very rtant and unexpected conclusion is the absence y evidence for regarding sepsis as playing a part ie incidence of pulmonary embolism This is iently surprising, and there are numerous other omena connected with this serious complication i are equally interesting and inexplicable We ot know why the clot should originate so often e left iliac vein, or why it does not occur equally ionly on the other side Often enough we cannot find the site of origin, when it is reasonable to ne that a minute clot, leaving no trace on the of the vein, has been held up in the cavities of the amongst the chordæ tendineæ, or in the auricular idage, until it has reached a large size before dislodged again into the circulation Two however, emerge from Dr Lister's study, it seem to be right to encourage free movements c limbs and to insist upon breathing exercises every abdominal intervention

ere is another aspect of Dr Lister's paper to i attention should be called, the paper is an in-tive example of a method of research which is y beginning to be appreciated at its true value ugh in these days there is no want of candidates for grants and appointments to research, there is undoubtedly a too widespread impression that no investigation is worthy of that name unless it involves the use of complicated technique and is pursued amid thousands of pounds' worth of apparatus Many young men—and some older ones—are in need of the rebuke addressed to Peter "What God hath cleansed, that call not thou common" The truth is that in such institutes of pathology as Prof H M Turnbull's department at the London Hospital there are accumulating records the analysis of which would throw light upon many obscure places Since such analyses involve the use of statistical methods, it is sometimes suggested that they should be handed over to professional statisticians This proposal we believe to be wholly unsound It is probable that an investigator who is not a professional statistician will sometimes make even serious mistakes in the choice and application of a method, but it is certain that the professional statistician not intimately acquainted with the material he is using and the subject he proposes to investigate will run still more serious risks At worst, the amateur statistician will overestimate the value of his conclusions and, if he fairly puts his cards on the table, others may judge for themselves The statistician not familiar with the subject matter will not know what cards *ought* to be put on the table Dr Lister has both clearly presented and sufficiently analysed his data His conclusions seem well supported by evidence, the strength and inherent weaknesses of which are clearly described The reports by Dr Janet Lane-Claypon, which the Ministry of Health has published during the last few years, illustrate the application of a like method to clinical statistics These reports and Dr Lister's differ in two ways from the similar papers which are often written as theses for university degrees The statistical treatment, without pretending to be more than elementary, is *at least* much superior to what has long done duty for statistical analysis in medical papers The scope of the data is immensely wider That is, perhaps, the crux So long as an analysis of *m* consecutive cases of such or such a disease is treated as a matter for a few hours' examination of documents and a few evenings' writing, this kind of research is rightly despised The tackling of data on the scale of Dr Lister or, a fortiori, of Dr Lane-Claypon, is quite another thing and requires much time and patience We hope that when the London School of Hygiene opens its teaching department of epidemiology and vital statistics (over which Prof Major Greenwood is to preside) it will gather as its research students not only public health men (in the strict sense), but also young pathologists, surgeons, and physicians resolved to work in the field which Dr Lane-Claypon and Dr Lister show *to be fruitful* It is regrettable that many hospital records are still badly compiled, it is even more regrettable that the good records are so little utilised

◆

DROPLET INFECTION AND CARRIERS

The little drops of water have, it seems, triumphed over the little grains of dust in current teaching regarding the source of *infection* in bacterial disease It is nearly 40 years since Flugge insisted that it was the shower of sputum droplets rather than the wafting of dried bacilli, championed by Fraenkel, which constituted the chief danger of contracting tuberculosis, and although in this disease the controversy may not yet have entirely died down, droplet infection is now accepted as the chief conveyer of the swifter infectious diseases Observations made by Capt J A GLOVER[1] on infection in cerebro-spinal fever were the starting-point of the more recent work The weakest link in the chain of infection lies in the transit of the virus in air-borne droplets from naso-pharynx to naso-pharynx, and Dr GLOVER showed how small an increase in the distance between the beds was sufficient to check the spread of infection in barrack dormitories Surg-Comdr SHELDON F DUDLEY, R N, remarks in a report[2] just issued that the study of infectious disease with its constantly changing distribution in time and space is really a problem in the physiology, ecology, and bionomics of bacteria The study of infection resolves itself into a study of three velocities (1) the velocity at which the infective material is received by the host, (2) the velocity at which it is destroyed by the host, and (3) the velocity at which the host s resistance alters in a positive or negative direction The new-born babe, however, does not need to acquire its resistance to an infected environment entirely by its own effort, it possesses a remarkable ready-made herd-immunity This transmitted passive immunity lasts long enough to tide the infant over its early unprotected stage, it is no longer operative at the age covered by Dr DUDLEY's studies

These studies were conducted in a semi-isolated community of about 1000 lads in naval training at Greenwich, varying in age from 11½ to 15½ years, and occupying sleeping quarters consisting of nine large airy rooms, each containing 70 to 126 beds, for the most part cross-ventilated and with a floor space averaging 40 sq ft and a gross air space averaging 500 to 600 cub ft per bed The distance between the ends of the beds was generally about a foot, the boys sleeping alternately head to foot In this community during the period 1912–24, or 38 school terms in all, the annual attack-rate reckoned per 10,000 boys was as follows Sore throat, 1378 (or more), influenza, 1200, scarlet fever, 334, diphtheria, 224, rubella, 140, mumps, 104, measles, 27, chicken-pox, 23, cerebro-spinal fever, 2 These attack rates, it will be noted, are much higher than among the general population, although length of residence altered the herd-immunity, reducing the rapidity of spread among the older residents Segregation was, however, completely successful when it could be carried out, even in the case of influenza, for there was none among 80 new boys during their period of isolation at a time when influenza was epidemic in the main school New entries join in batches of 30–50 two or three times a term and are kept quite separate for 3–4 weeks in a separate building with grounds of its own This experience with isolation agrees with that of the Australian naval authorities, that absolute quarantine of ships, although it may be inconvenient, is certainly effective in preventing the spread, even of influenza, from ship to ship or shore The chief anxiety at Greenwich is in regard to diphtheria and scarlatina Over the whole period the incidence of diphtheria was more than four times that prevailing in a slightly younger group of London school-children, and in 1921 as much as 20 times greater, although on entry these children possessed the degree of herd-immunity common to their age It follows that the best specimens of council school-boys, transferred to the new environment at the Naval School, suffered from a morbidity more than fourfold that of boys who remained in the original environment The figures for scarlet fever told the same story, and confirm Dr DUDLEY's view that most microbic dissemination takes place in the sleeping quarters, where time is provided for the collection of an infective dose of parasites Only one outbreak of mumps of any magnitude occurred in the 22 terms, the incubation period is so long that, unless the outbreak starts very early, it is liable to be cut short by the intervention of holidays before a sufficient number of centres of infection have developed Rubella was responsible for two outbreaks with an onset so explosive that it could only be explained by supposing that the recorded cases were infected by missed cases or carriers The chief practical lesson which Dr DUDLEY draws is that the individuals of a community should be isolated from each other to the greatest extent possible in their sleeping quarters GLOVER s work showed that meningitis could be prevented and the meningococcus carrier-rate reduced to about 6 per cent by increasing the distance between adjacent beds to 2 ft 6 in, a distance insufficient to prevent outbreaks of diphtheria or scarlet fever, whereas by the time the recruits go to sea herd immunity for these infections has become so high that no serious outbreak has occurred in any British warship in spite of the close sleeping conditions (Diphtheria did, however spread from hammock to hammock among the unsalted crew of an American battleship at Scapa Flow) The experience of bed-isolation teaches that young children will rarely infect each other with diphtheria or scarlet fever when there is 9 ft between the beds, although even 12 ft will not prevent cross infection with early measles and chicken pox It is, therefore, impossible to lay down any standard distance that will prevent the spread of infectious disease between beds for the minimum distance varies with the variety of host and parasite and with the previous amount of microbic experience possessed by the host The best method of reducing morbidity from droplet dissemination would, of course, be a separate sleeping room for each individual Otherwise, even when the Greenwich school moves into country quarters and the occasions on which fresh infections are introduced are fewer, a bigger attack-rate at longer intervals may become the rule among a population whose herd immunity has become low

In regard to this herd-immunity, Dr DUDLEY makes many interesting suggestions As we began by mentioning he finds three variables necessary to explain the relation between the carrier and the herd-immunity which he produces A certain mass of infective agent is necessary to produce an illness This mass may be received at various rates by an individual who can only destroy the virus at a certain rate If this difference is positive, illness will supervene, provided the stay in the infected atmosphere is long enough If this velocity is negative no actual illness occurs although the defensive mechanism of the recipient host may be stimulated so as to make him immune to more serious infection later Other factors being equal, it will depend on the distance of a susceptible host from a distributor of parasites as to whether the host becomes a case, a carrier, or an immune person Acting in a suitable environment, carriers may prevent large disease outbreaks by supplying subinfective doses of infectious material to the more susceptible members of a population The whole problem becomes simpler if the carrier state is envisaged as the mildest form of a clinical disease entity—namely, as a disease without symptoms

THE SPAHLINGER TREATMENT

A FORTNIGHT ago we published a detailed clinical record by Dr THOMAS NELSON of certain cases treated by the Spahlinger method at St George's Hospital 12 years ago. This communication was in pursuance of a settled policy of printing, without curtailment or comment, all records of cases, successful or unsuccessful, treated by this method, when submitted to us by medical men. As this policy has been criticised, we take the opportunity of setting out again the principles which dictated it, they are contained in a leading article which appeared in THE LANCET of Feb 17th, 1923, and is here reprinted word for word.

The position of the Spahlinger treatment has reached a stage which would be comic, were it not so supremely tragic—our French neighbours would certainly term it an *affaire*. The bactero-therapeutic institute at Carouge, near Geneva, is fully equipped with the most recent apparatus for serological and bacteriological research, it includes an experimental farm, and the whole installation would reflect credit upon a large scientific institution or university. It has been controlled and directed for ten years past by Mr HENRI SPAHLINGER, who has trained an efficient staff in his own special methods. Precisely what his claims are, in the cure of tuberculosis, were set out in his own words in our issue of Jan 7th, 1922. All who have visited the institute—and the visitors have been many and distinguished—have been favourably impressed with the character of Mr SPAHLINGER'S work and with his sincere desire to put his remedies at the disposal of mankind. The remedy has not yet reached the stage of proved value and necessity. Mr SPAHLINGER himself does not pose as a clinician, and the clinical trials of his remedies have been spread over several countries and have nowhere been carried out under research conditions. It is well known that the British Ministry of Health is prepared actively to encourage the experimental trial of the Spahlinger preparations under scientific supervision, so soon as supplies of the remedy are available for the purpose, and the British Red Cross has gone so far as to vote a sum of £30,000 to enable Mr SPAHLINGER to produce his remedies to a larger extent so that they may be tried in this country.

The issue being thus clear-cut, it is with the keenest regret that we have noted during the last week evidences of a press campaign to raise funds in this country on the ground that the reports already published prove beyond doubt the great national importance of the movement. A Memorandum ostensibly prepared by several medical men as an authoritative statement of facts, contains such regrettable exaggerations as that the methods of SPAHLINGER make it clear that tuberculosis can be prevented, and that when the treatment is over there is no trace of the disease remaining. There is a suggestion that, had they not been prevented from doing so by the fear of "oblique advertisement" (in the sense of the General Medical Council), many important signatures would have been appended to this statement. It seems to us improper to infer the weight of medical opinion in such a way. The Ministry of Health has found it necessary to reissue a statement of its position—namely, that up to the present the Minister has neither approved, nor disapproved, of the treatment.

The Memorandum justifies the appeal for funds by the grave danger from financial pressure to which Mr SPAHLINGER'S work is now exposed. We can only trust that he will submit to the independent investigation of his remedy which would put him right with the medical world and relieve him of his immediate difficulties. Could some arrangement be made to carry out this investigation, with the usual controls at one or other of the research institutes in this country, two objects would be served (1) the money could be raised without risk of forfeit, and (2) the control would bring conviction to those among whom it is carried out. We appeal to Mr SPAHLINGER in the name of humanity, no less than in that of science, to consent to this course.

The situation does not seem to have altered appreciably during the four years since these words were written. The money has indeed been returned to the Red Cross, but the offer by the Minister of Health of a thorough test of Mr. SPAHLINGER'S remedies in this country has never been accepted by him although Sir W A ROBINSON has stated within the last few days that Mr SPAHLINGER is well aware of the Ministry's willingness to arrange for an immediate investigation and test of his remedy at any time. Mr SPAHLINGER himself writes of visiting England early this year for the purpose of carrying out demonstrations with his bovine vaccine, the sale of which can soon provide (as he has stated in a correspondence with Sir WARDEN CHILCOTT in the *Daily Express*) all the funds required. There is, of course, nothing new in a claim to have immunised cattle against experimental infection. v. BEHRING'S success with his bovo-vaccine in 1902 has been since confirmed by R KOCH, P H RÖMER and T M KLIMMER in Germany, L PEARSON in America, A CALMETTE and C GUERIN in France, but we believe that neither they nor anyone else has yet succeeded in establishing permanent immunity to accidental infection from diseased cattle in the same shed. We again appeal to Mr SPAHLINGER to submit his remedies to independent investigation, which is the only way to right his position with the medical world, and thus relieve him of his difficulties.

◆

STANDING MUTE OF MALICE

ON Jan 6th at the West Sussex Quarter Sessions at Chichester, a man charged with breaking into and entering the Territorial Drill Hall at Worthing and stealing money and cigarettes therefrom refused to reply to the charge. It was then necessary to empanel a jury to decide whether he was 'mute of malice' or "mute by the visitation of God". Dr W WATSON, senior medical officer of Brixton Prison, who had been keeping the accused man under observation, gave evidence to the effect that the prisoner had spoken normally until four days before the trial but had suddenly adopted this strange silence after receiving a letter which seemed to upset him. The jury took the view that the accused could speak if he liked, he was found guilty and was sentenced to 18 months hard labour. According to the report of the case in the *Times*, he never spoke once during the trial.

The psychology of the individual in the Chichester case is interesting, so, too, is the national psychology as revealed in the strange story of English criminal procedure which the words "standing mute of malice" recall. If we go far enough back in our history we find in England, as in so many other primitive communities, that the test of guilt or innocence is governed by some form of ordeal. It is a judgment of divine providence. The Church has its ritual for consecrating the elements of fire or water which are to reveal the truth. The water in the pit, says MAITLAND, is adjured to receive the innocent and reject the guilty. He who sinks is safe, he who floats is lost. The red-hot iron, 1 lb in weight, must be lifted and carried three paces. The hand that held it is then sealed up in a cloth, three days later the seal is broken. Is the hand clean or foul? A blister 'as large as half a walnut' is fatal. We do not know how the tests worked in practice, but WILLIAM RUFUS was sceptical enough to say, "God shall no longer judge these matters; I will do it myself." The Norman conquest had introduced another form of ordeal—the judicial combat. Accuser and accused fought it out, the accuser undertaking to prove by his body the truth of his charge. Meanwhile, there was a royal system of inquest, a primitive form of trial by jury, which made headway, being preferred to the ordeal by battle which was never a poor man's remedy and would not work if the appellant was a woman, a child, or a cripple. In 1215 the Lateran Council forbade the ordeal, and Rome at that time had power enough to dictate to England. With the ordeal disappearing and trial by jury taking its place, it was, nevertheless, some years before the new judicial procedure was standardised. If a man refused to "put himself upon his country"—i.e., to stand his trial before a jury of his peers—there was an inclination to regard his case as undefended and himself as guilty. It was one of the customs of Normandy that a man charged with murder was kept in prison for a year and a day with little to eat or drink unless he submitted to the verdict of an inquest. In England the suspected felon was similarly placed in rigorous confinement, though without the time-limit of a year and a day; he was put in irons and made to lie on the ground in the worst place in the prison; he had a little bread one day and a little water the next. All the while there was a notion that this was not quite fair. The man had been deprived of his ancient, natural right to a judgment of God. However, if he would not agree to be tried by jury, he could be starved into consent. A few years later worse barbarities were perpetrated in the name of justice. The man was laid out naked upon the floor and heavy weights were piled upon his chest until the poor wretch agreed to abide by the verdict of his fellows. This was called the *peine forte et dure*, and men were stubborn enough, even in the seventeenth century, to be thus pressed to death unconvicted rather than run the risk of being hanged as felons in which case their property would be confiscated and their children would be penniless.

Alienists who desire to see a change in the present legal view of criminal responsibility of the insane will know that the law is marvellously conservative. The history of the *peine forte et dure* illustrates this same conservatism, for that hideous piece of legal cruelty was not formally abolished till 1772, when refusal to plead in cases of felony was made equivalent to a plea of "guilty." Another change took place in 1827 when refusal to plead, if the defendant was not mute by the visitation of God, involved the entry of a plea of "not guilty." This meant that the jury must first say (as in the recent case at Chichester) whether the defendant stands mute of malice or is mute by the visitation of God. If found mute of malice, then he is tried as on a plea of "not guilty." If mute by the visitation of God, the jury must further say if he is fit to plead and able to understand the proceeding at the trial. If they reply in the negative, he is treated as insane. To proceed with the trial in such cases would be a burlesque, but it is naturally deemed a strong step to order a man to be confined as a criminal lunatic when he has not been found to have committed any criminal offence. The standing orders of the Prison Commissioners recommend that a prisoner should be left to stand his trial unless there are strong reasons to the contrary. The Atkin Committee, appointed to examine the general relation of insanity and crime after the case of RONALD TRUE, approved these standing orders and added its opinion that an accused person should never—except in the plainest cases—be found unfit to plead except upon the evidence of at least two doctors. The Committee also advised that there should be no appeal from a finding of unfitness to plead. The verdict "mute of malice," therefore, is a link with far-off times when it was first found necessary to insist that an accused person should make his plea one way or the other. To round off the story, it remains to add that ordeal by battle lingered on as late as the year 1819. Described in the fourteenth century as though it was already a curious anachronism, mentioned as obsolete by a lawyer in the reign of ELIZABETH, this rusty relic of the law was resuscitated in Ireland in 1815 where a criminal claimed his right to do battle with his accuser and thereby escaped. Four years later, in England, ABRAHAM THORNTON had recourse to it and thus evaded the consequences of a conviction for murder. This was too much for the national conscience, and ordeal by battle was formally repealed by Parliament in the following year. Changes in English criminal law, it will be seen, come slowly.

◆

EBERTH

THE name of Carl Joseph Eberth will long be remembered because he was the first to describe the causal organism of typhoid fever. Born in 1835 he had made his mark in pathology long before his great discovery was announced. His early work in Würzburg was mainly on the smaller blood-vessels and especially on the development of capillaries in the skin and lung. Studies of the bacterial mycoses led up to the search for some organism constantly associated with the clinical manifestations of typhoid fever, and in Virchow's *Archiv* in 1881 he described rod-like bodies "about the same size as those which are met with in decomposing blood, but differing from them in shape and staining properties." In six out of 17 cases of typhoid fever he was able to demonstrate the bacilli, finding them most readily in the intestine and lymph-glands at an early stage of the infection. These observations left no doubt that the bacillus was in some way connected with the disease, although it required the subsequent experimental investigation of Gaffky to demonstrate them as the actual vehicle of contagion. Apart from his work on typhoid, Eberth wrote on various aspects of pathology, notably on amyloid degeneration and malignancy. Many years of his life were spent in Zurich where he was appointed prosector in the University and later professor of pathology at the Veterinary College. In 1881, however, he returned to Prussia and occupied the chair of histology and pathological anatomy in the University of Halle. He died in Berlin last month in his 92nd year.

STREET ACCIDENTS IN MANCHESTER.—There were 76 fatal street accidents in Manchester in 1926, as compared with 59 in 1925. The non-fatal accidents in 1926 numbered 2045 as compared with 1727 in 1925, and 1655 in 1924. This means an increase of 300 accidents in 1926. One remarkable feature of the accidents reported was that no fewer than 425 non-fatal and 25 fatal accidents—or about 20 per cent. of the whole number reported to the police—were due to persons stepping off the footpaths in front of approaching vehicles. During the period of the general strike in 1926 there was an increase of all accidents of about 40 per cent. over the corresponding period in 1925. In the 2045 non-fatal accidents during the year 496 of the injured persons were under 15 years of age. In the street accidents of 1926, the following vehicles were involved: tramcars, 291; taxicabs, 74; private motor-cars, 787; motor-cycles, 327; other mechanically-propelled vehicles, 328; horse-drawn vehicles, 122; and pedal cycles, 532. Whilst there were 33 non-fatal accidents attributable to pillion-riding, no fatal accidents from this cause were reported. During 1926 drivers' licences were issued to no less than 31,183 residents in the city—the number being over 4 per cent. of the total population.

Annotations.

"Ne quid nimis"

RACIAL IMMUNITY.

To recent issues of *Man* Colonel J Cunningham, I.M S Director of the King Institute in Madras, has contributed a review[1] of the factors of racial susceptibility and immunity to disease The problem has attracted attention ever since medical men with a Western training began to move about the world and observe the differences with which the various diseases they found affected the several varieties of mankind There are in the literature a good many statements that susceptibility to this or that infection varies with race, but only recently have workers realised the difficulties of being sure that these variations are really linked with the anatomical and physiological characters which make up racial differences, rather than with the sanitary state and circumstances the habits and modes of life which normally accompany them It is easy enough to show that, starting with a single pair of guinea-pigs, races may soon be obtained by in-breeding which differ in the most definite way in their susceptibility to inoculated tubercle In such experiments the animals live side by side. their surroundings are identical, and they differ in nothing but their genetic constitution But in man the world seldom if ever yields us a comparable example of two races living side by side with no significant difference except their inborn nature It is of course, obvious that the rarity of scarlet fever and the frequency of malaria in India tell us nothing of the relative susceptibility of English and Indians to these diseases Nor does a direct comparison of Englishman and Indian in India give us a straightforward answer Beri-beri for example is almost unknown except in natives, and if their habit of getting a large part of their energy from decorticated rice is not the whole explanation of the incidence of the disease among them it gives us a satisfying reason why the English living alongside them escape it altogether Similarly, kangri cancer in Cashmir is no more truly racial than is mule-spinners' cancer in Lancashire It is evident that the two races living in the same country must live the same lives if valid comparisons are to be obtained Even if superficially there is considerable similarity, detailed knowledge may bring to light effective differences Of this Colonel Cunningham gives a good example in a town in Southern India, where Hindus and Mahommedans lived in the closest proximity and yet kala-azar occurred only among the latter who were traders and moved about the country while the agricultural Hindus stayed at home where social and religious barriers prevented any close personal intercourse of one sect with the other Similarly. it is not fair to deduce racial differences in susceptibility from a comparison of the negroes and whites in the United States without a full appreciation of the generally deteriorated position of the coloured part of the population, industrially and socially, and all the consequences which that involves It seems likely that the almost universal occurrence of rickets in negro babies in New York is as near a racial character as can be expected, for it is no doubt largely due to their pigmented skins which are beyond their control but without further investigation we cannot measure the concurrent importance of their financial and residential condition over which they and their fellows could exercise some choice Finally. Colonel Cunningham mentions another factor of great importance which is necessarily more complicated It is now being realised more and more that human populations and especially dense urban populations, have come into some sort of balance with the infectious diseases to which they are exposed partly by progressive selection and partly by active immunisation by subinfections in early life The population of London for example, has become as a whole resistant to measles just as the rat population of India has, during the last 30 years, become resistant to plague If Londoners had been living in the Faroe Islands in 1846 they would not have suffered very much from the epidemic of measles which smote three-quarters of the natives It follows that two races living together cannot be properly compared for resistance unless they have been equally selected and immunised, in other words, their past history is germane as well as their present circumstances Considerations of this kind may well explain the easy susceptibility of negroes to tuberculosis, in the end they may become as resistant as the whites living with them. This effect of exposure to infection also has its influence on the parasite, though the change will generally take place much more quickly The spirillum of a primary attack of relapsing fever is different racially from the spirillum which is obtained from a relapse in the same patient, the parasite has adapted itself to the resistance of its host by selective breeding The balance of an established infectious disease concerns, therefore, both parasite and host. Such are some of the difficulties which surround the solution of a most interesting problem, they are not less than the obscurities in which most questions of human energies are involved But if the difficulties and necessary precautions are clearly realised, there is no reason why they should not be solved

INTRACARDIAL INJECTION OF ADRENALIN

METHODS of reanimating a presumably healthy heart that has suddenly ceased to beat, as for example, in syncope during anæsthesia, have been many and various and their multiplicity indicates the uncertainty of their results The statistics collected by Dr Carl Bodon, recently quoted by Dr. Harrington Sainsbury (see p 134 of this issue of THE LANCET), and the experimental researches of R Gottlieb and J Winter on the direct injection of adrenalin into the heart itself seem to prove that this method has certain indisputable advantages over simple massage, electrical stimulation, and injection of saline A review of the whole subject by Prof L Manfredo[1] will interest all who have been faced with the need of reanimating a heart in a temporary state of suspended function The stimulating effect of adrenalin on the heart induced Gottlieb to try this drug for the purpose and he succeeded by using intravenous injections in restoring action in rabbits poisoned by chloral, chloroform, or potassium. Practising at the same time direct massage of the heart, he reanimated even hearts which had completely ceased to beat and in which heart massage and artificial respiration alone had proved ineffectual The use of adrenalin intravenously when the heart is arrested necessitates massage of the organ in order that the drug can reach the heart itself It will be understood that to enable concentrations of adrenalin sufficient to act as a stimulant to reach the heart, a vein near the organ must be selected for small doses, and the farther the vein is from the heart the larger must be the doses employed G W Crile, by injecting 20 and 10 mg respectively in two wounded persons who were in a state of syncope from stovaine spinal anæsthesia, and practising at the same time cardiac massage, obtained a permanent good result The effect of adrenalin seems to be the same whether it reaches the right or left cavities the myocardium or the pericardial sac The first attempts on the human subject, inspired by the experimental researches of Winter, aimed at reaching the left ventricle, but technical difficulties and theoretical ideas induced most surgeons to reach the right ventricle; it does not appear from published reports that it is of much importance which is selected As to its precise mode of action very little definite is known Against the old conception of Gottlieb who, from his experiments on frogs hearts, affirmed that adrenalin acted not on the muscular fibre but on the autonomous nerve centres of the heart, stands the other conception of Grandis that it is a drug of pre-eminently muscular action Coronary circulation does not seem necessary in order that the adrenalin may reach the nerve centres or the muscle-fibres on which it acts, in fact its action is just as rapid and intense when it is injected into cardiac cavities That is to say that the lymphatics of the heart diffuse the drug rapidly to its points of attack And since the injection is efficacious in either the right or left side of the heart, it must be inferred that adrenalin stimulation of one of the centres, or of a group of fibres, is sufficient for the first contractions Considering that the normal seat of stimulus formation is the Keith-Flack node between the opening of the superior vena cava and the right auricle, and that from this point the stimulus passes to the fibres of the myocardium, at first across the auricular-ventricular node of Aschoff-Tawara, a place near the opening of the coronary sinus in the right auricle, and then across the bundle of His, it is easy to understand the preference given by many to injection into the right side of the heart. The fact that any cardiac centre may, when required, produce the stimulus for cardiac activity, explains the success of injection into the right side of the heart The puncture should naturally avoid wounding the interventricular septum from which diverge the two branches of the bifurcation of the bundle of His, and the site of Kronecker's point It is interesting to note, moreover, that while in a general sense adrenalin is vaso-constrictor, it seems to be a vaso-dilator of the coronaries, by which it helps cardiac irrigation and returning function From the foregoing data it appears that the best place for making the puncture is the anterior surface of the right ventricle at some distance from the base and interventricular septum so as to avoid the anterior coronary vessels This point corresponds to the fourth left intercostal space at the upper margin of the fifth intercostal cartilage close to the sternal margin, and on injection artificial respiration is for the moment arrested in the expiratory phase to avoid wounding the lung The course of the needle should be at first perpendicular to the thoracic wall for 2 or 3 cm, then slightly inclined towards the median line when the resistance of the heart wall will be felt, with another 0 5 cm the right ventricle is reached as shown by aspiration into the syringe The injection of 1–3 c.cm. of 1 in 1000 solution should be made slowly and artificial respiration is resumed as soon as the needle is withdrawn The method has had its greatest successes (50 per cent) in cases of syncope from chloroform or ether or spinal anæsthesia, and certain cases of narcosis, artificial pneumothorax, and asphyxia In the field of pure medicine where organs are diseased the possibilities of success are very much diminished, but favourable results have been reported in the white asphyxia of the new-born and in the syncopal attacks of Addison's disease

THE DISEASES OF AMAZONIA

This recently published volume[1] contains an account of the medical results of the seventh expedition to Amazonia which was made possible through the generosity of Dr Hamilton Rice The medical investigation described was for the most part carried out in the cities of Manaos and Para and their vicinity, and concerned the diseases met with in the course of certain geographical explorations The prevailing maladies in the regions traversed by the expedition were malaria, tropical splenomegaly, chronic ulcerations of the skin, leprosy, and syphilis Hookworm disease, beri-beri dysentery, typhoid and small-pox were also encountered Members of the expedition, which at times included some 30 persons, were evidently impressed with the robust health of the Maku Indians in spite of the primitive conditions of life in these native settlements There are no screened houses or mosquito nets, no hygienic measures as regards the disposal of excreta or the care or sterilisation of drinking water, there are no physicians, or drugs, or chemists' stores, and yet, generally speaking, the inhabitants living upon the river banks do not show evidence of either acute or chronic disease The Brazilian strain of *Leptospira icteroides* produced fatal infections in young dogs, while the sera of persons who had recently recovered from attacks of yellow fever gave positive Pfeiffer reactions when tested with strains from sources in Ecuador, Mexico, Peru, as well as with the Brazilian strain These results tended, therefore, to confirm those of Noguchi Tropical sloughing *phagedæna* was frequently encountered and a considerable amount of evidence obtained for connecting *Spirochæta schaudinni* with this disease Striking cases of oral leishmaniasis were encountered A subject of very considerable interest was the discovery of a disease which the authors designate "tropical splenomegaly" on the Upper Amazon and Rio Branco They are convinced that this is a disease *sui generis* and not a peculiar form of schistosomiasis It is certainly not kala-azar or any of the other well-known causes of splenomegaly, and appears to be confined to children who are otherwise in good health The remainder of the lengthy report is mainly concerned with animal pathology There are descriptions of trypanosomiasis in horses, in the indigenous fauna, and blastomycosis and parasitic infections of the wild animals of the Amazonian forest A new cestode, *Atriotænia parva*, of the Coati, *Nasua socialis*, is described The large entomological section is mainly of technical interest A list of birds, beasts, reptiles, and fishes seen on the Branco, Uraricuera, and Parima rivers terminates a report which supplies much useful information and redounds greatly to the credit of the Tropical Section of the Harvard Medical School.

EARLY ANATOMICAL STUDIES

A band of enthusiastic scholars is now doing for anatomy what the late Dr Nicaise did so well for surgery a few years ago Karl Sudhoff, at Leipzig, Charles Singer in England, H E. Sigerist in Zurich, and E Wickersheimer at Strasbourg are elucidating the history of mediæval anatomy by publishing the original texts which have long been known to those interested in the subject, but rather by repute than by actual study, for they have been hard to get and difficult to read The "Anatomy" of Mundinus is already familiar because it bridges the interval between the theoretical knowledge of the Alexandrian school, as transmitted through Salernum, and the "Anatomy" of Leonardo da Vinci and Vesalius Mundinus is honoured because he actually dissected the human body when it was both dangerous and difficult to get subjects Guido Vigevano is less well known, except to readers of Dr Singer's FitzPatrick Lectures of 1923–24 He lived a generation later than Mundinus, whose pupil he may have been Where Mundinus describes at length, Vigevano illustrates by drawings, and an idea is thus obtained of the anatomical technique of the period. Prof Wickersheimer has worked hand-in-hand with his publisher and the result[1] is worthy of all praise The Mundinus facsimile is from the 1478 edition printed at Pavia and reproduced from the copy in the Library of the British Museum Vigevano's Anatomy is represented by 16 plates, of which four are in colour, with a valuable apparatus criticus The work is issued in a limited edition as the third volume of a series of "Documents scientifiques du XVe siecle," printed by F Paillart, of Abbeville and published

by E. Droz, in sheets contained in a portfolio, and it reflects the highest credit both on the good taste and energy of the publisher. We should like to see a similar issue of Mirfeld's "Breviarium Bartolomei" or of Arderne's "Practica Medica," both of which are crying out for print after centuries of seclusion in manuscript.

SUPERINFECTION OF MAN WITH SYPHILIS AND YAWS

FOLLOWING up a long-standing controversy, Dr. Takashi Hashimoto,[1] of the Japanese University at Mukden, Manchuria, has recently succeeded in superinfecting with syphilis 20 human subjects already suffering from proved syphilis in various stages. The inoculum was obtained from papules, condylomata, pustules and gummata from the subject himself or from others. It was injected into the skin on the flexor surface of the arm, and a control injection of the same material, sterilised by heating, made at the same time into the skin of the other arm. Both inoculations produced redness and local œdema, which was less marked and disappeared sooner on the control side. A positive infection was denoted by marked local adenitis and development of progressive redness and infiltration at the inoculation site, sometimes after a preliminary disappearance of the initial redness and swelling. Later the infiltration became nodular and ulcerated, the lesion then resembling an indurated chancre or a gumma. All the subjects were kept without treatment for four weeks or longer after the inoculation. In some a second or third inoculation was successful after the first or second had failed. In all but two of these inoculated superinfective lesions *Spirochæta pallida* was easily demonstrated. Although the patients were in various stages of syphilis, the superinfective lesions did not as a rule correspond in character with that stage of syphilis borne by the individual inoculated. Seven cases (including primary, secondary and tertiary stages of syphilis) were inoculated with material from syphilitic lesions in other patients; positive results were obtained when the material inoculated came from a lesion of an earlier stage of syphilis than that presented by the subject inoculated. In eight of the positive cases biopsy of the inoculated lesion was carried out, and the typical histological changes of syphilis were found in all of them; the *S. pallida* was found in six. The development of a syphilitic lesion in the skin at the site of recent trauma in a syphilitic has often been observed. The effect of trauma is excluded in Dr. Hashimoto's experiments by the failure of the control inoculations. Drs. G. R. Lacy, A. W. Sellards, and O. Scholl have carried out superinfection of human beings with yaws.[2] Four patients with this disease were treated with neosalvarsan and, after an interval of six months, inoculated with yaws. One developed a characteristic granuloma, the others showed atypical results. Treatment with neosalvarsan was repeated in two cases; in the other two the lesions disappeared spontaneously. After more than two years these four patients were found to be free from any clinical signs or symptoms of yaws, and their Wassermann reaction was negative. They were then reinoculated with yaws, and only one developed a typical granuloma—the same one who was found susceptible in the previous test. At the time of the first neosalvarsan treatment this patient had had yaws for only three months; the others had had it for much longer periods and showed definite resistance to reinfection with yaws. The conclusion is that active immunity develops late in the secondary stage of yaws. It is of considerable practical significance that patients with yaws treated in the advanced secondary stage have remained in excellent health, free from any sign of the disease and that they retained marked resistance to reinfection for more than two years, for this period is ample to permit bringing the disease under control even in heavily infected districts. In further experiments six volunteers were inoculated with yaws; five developed a typical granuloma at the site of inoculation. On reinoculation of the five patients four to six weeks after the first inoculation a lesion developed at the site of reinoculation which clinically was granulomatous, and spirochætes were found in it. The sixth patient of this group showed only an abortive reaction at the site of the first inoculation, but later a secondary eruption appeared. Lacy, Sellards, and Scholl noted that the primary efflorescence in yaws, as in syphilis, is a papule. In syphilis this papule leads to formation of a punched-out ulcer, whereas in yaws it becomes an oozing granuloma covered by an amber-like crust.

THE RADCLIFFE INFIRMARY

THAT eminently shrewd and successful practitioner Dr. John Radcliffe, besides furnishing funds for the endowment of two travelling fellowships, giving £5000 for adding to the buildings of University College, Oxford, £40,000 for a library in the University, and £500 per annum to St. Bartholomew's Hospital, left his estates in Yorkshire, Buckinghamshire, Northamptonshire, and Surrey in trust to his executors "to be applied to such charitable purposes as they in their discretion shall think best." This duty they and their successors have carried out with admirable charity and discretion. Radcliffe died in November, 1714; the Radcliffe library was opened in 1749, and in the *London Chronicle* of July 15th, 1758, appeared the following notice:—

> "The Radcliffe Trustees have agreed to erect a County Hospital here (i.e. Oxford), and Mr. Rowney has generously made them a present of a piece of ground of five acres for that purpose."

The original grant had been made by the trustees on April 26th of the same year, the sum voted being £4000; the inceptors of the scheme were most probably the Earl of Litchfield, one of the trustees, and a country neighbour of his named Thomas Rowney. Another likely inceptor is Richard Frewin, Camden Professor of Ancient History and a practising physician in Oxford. Lord Litchfield will ever be held in remembrance by the ward in the infirmary named after him, by his endowment of a clinical professorship of medicine at the infirmary, and by the readership in anatomy. Frewin also left £2000 the interest of which was to be and still is paid to the infirmary physicians. As generally happens the initial cost of the buildings far exceeded the £4000 originally voted. The building was opened for the reception of patients in 1770, and between 1758, when the scheme started, and 1779, the total cost, including sundry furniture, was £12,791. Also as generally happens, the builder in 1764 announced that the building would be completed by midsummer and in 1767 that it would be finished by Michaelmas. Dr. Gibson in a recently published volume[1] gives a full account of the government of the infirmary which, though not technically part of the University, was and is in close touch with it. Perhaps the most interesting passages of the book to professional readers are the biographies of the medical and surgical staff, which are full of charming vignettes of social aspects of the eighteenth and early nineteenth century. Thus one of the physicians, William Thomson, D.M. 1786, was public Reader in Anatomy. In 1790 two murderers having been hanged in the morning, in the afternoon—

> "their bodies were conveyed in a cart to the Anatomy School at Christ Church, where Dr. Thomson next day gave a public lecture on the two bodies, to which the neighbouring faculty as well as those of the place were invited, together with the gentlemen of the University and many of the principal inhabitants."

In the notice of Dr. Robert Bourne, Dr. Gibson gives some interesting details of an interview which

[1] The Radcliffe Infirmary. By Alexander George Gibson. Oxford University Press. London: Humphrey Milford. 1926. Pp. 316. 18s.

Bourne had with Howard, the prison reformer, who had expressed himself as displeased with the condition of the wards Later we find in the note on C L Parker, one of the surgeons (M R C S 1831), that on one evening—

> "I (Bishop Hobhouse) invited Mr Lewes Parker, a leading Oxford surgeon, who had lately shewn his skill in the treatment of the venerable President of Magdalen College, Dr Routh, who had been bitten by his gardener in a fit of madness"

The date of this tragedy is not given, but since Parker died in 1848 it is evident that his treatment must have been successful, for Dr Routh died in his hundredth year in 1855 The nursing staff, though not always as efficient as it should have been even in the eighteenth century, must have been cheered by the following incident which reflects gravely on the medical staff as well The *Oxford Journal*, of Dec 13th, 1777, reports—

> "On Monday last died in our Infirmary, Martha Jewell, a young woman admitted about five weeks ago, under Pretence of being troubled with a Dropsical Disorder, some hours before whose death, upon examining the Girl's Box under her bed, a female child was found wrapped up in a quilted petticoat, of which it appeared she had been privately delivered From Circumstances upon Examination before the Inquest it appeared that she had been delivered eleven days before her death"

This book should be read by every Oxford medical graduate, moreover, anybody who cares for the past history, not only of medicine, but also of varied aspects of social life, will find vivid pictures within Dr Gibson's carefully written pages

EXPERIMENTS IN PARABIOSIS

ARTIFICIAL union of two individual animals has been used from time to time in the study of various pathological problems, but only in the last few years has any attempt been made to employ this method in the elucidation of the various endocrine gland inter-relationships A considerable amount of work has now been done and the results are of interest, even though it would seem that this method of investigation is not likely to lead to any very striking results in problems of this sort The method of producing experimental parabiosis consists in uniting or grafting two animals of the same species, generally white rats, so that interchange can take place between the circulating fluids of the two organisms This is usually done either by musculo-cutaneous or peritoneo-cutaneous suture The condition is sometimes known as symbiotic grafting or, more simply, the animals joined may be referred to as a Siamese pair Several groups of workers have attacked the problems of endocrine inter-relationship by this means, the favourite experiment being by union of animals of different sex There has been general agreement as to the findings in such experiments, but a considerable difference of opinion as to their interpretation Changes occur almost universally in the sex and associated glands R Matsuyama, a Japanese investigator, was the first to study this aspect of parabiosis[1] Employing Siamese pairs of different sex he noted invariably that degenerative changes occurred in the sex glands of both male and female after a short time These changes were shortly followed by changes in the adrenals, pituitary and mammary glands He was inclined to consider that all changes followed a primary disturbance in the sex glands, the result of an antagonism between the hormones of the testicles and ovaries He regarded the condition as one of reciprocal auto-castration, and thought this view was confirmed by the fact that the changes in the other glands mentioned were the same as those found in castrated animals Although Matsuyama's findings have been confirmed by most subsequent workers, his conclusions have been the subject of considerable criticism, and none of his critics agrees with the view that the changes found are the result of antagonism between the hormones of the sex glands. The most popular view is that the changes result from a mutual intoxication between the internal metabolisms of the two organisms, and are not specifically related to the sex hormones The latest experimental work of G. Pighini and M de Paoli in Italy seems to confirm this[2] They have carried out a number of parabiotic experiments with male and female pairs, and they found a very marked reaction to parabiosis almost immediately after operation, a reaction which rather suggested an acute and mutual intoxication of the nervous system of the pair. This was apparently modified later by some degree of mutual immunisation, though the latter was insufficient to prevent emaciation and death Intoxication was less obvious in pairs operated on when very young, in the first two months of life, and in those born of the same litter, but it was always accentuated when the members of the pair were old or of different families Pighini and Paoli's anatomico-pathological findings corresponded with those of Matsuyama The post-mortem changes found in the glands of internal secretion were well marked There was a general tendency to degeneration and atrophy, first seen in the thymus, then in the sex glands, and later in the pituitary, thyroid, and adrenals The changes found varied in proportion to the toxic reaction to parabiosis These facts are certainly more readily explained on the hypothesis of a mutual intoxication of internal metabolisms than on a primary and specific antagonism between the sex hormones

WE greatly regret to inform our readers that Sir Ernest Hodder-Williams, our Chairman, was taken seriously ill last week At the time of going to press a position of slight improvement was being maintained

INDEX TO "THE LANCET,"
VOL II, 1926

THE Index and Title-page to Vol II, 1926, which was completed with the issue of Dec 25th, is now in preparation A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —The Fellowship has arranged clinical demonstrations in Ophthalmology at the Royal Eye Hospital, Southwark, by Mr Letchworth (Jan 17th), Mr Griffith (Jan 19th), Mr MacCallan (Jan 20th), and Mr Dorrell (Jan 21st), they will be held at 3 P M On Jan 19th Mr Duncan Fitzwilliams will give a special demonstration in the wards at St Mary's Hospital at 2 P M All these demonstrations are open to members of the medical profession without fee A comprehensive course in venereal diseases will be given at the London Lock Hospital from Jan 31st to Feb 27th Also beginning on Jan 31st there will be a four weeks' course at the St John's Hospital for Diseases of the Skin, *consisting* of instruction in the out-patient department and bi-weekly lectures Classes in pathology can be arranged From Feb 7th to 19th an all-day course in Diseases of Children will be held, in which the *Paddington* Green Children's Hospital and the Victoria Hospital are participating The Royal Northern Hospital is *holding* a one week's course for general practitioners from Feb 21st, *no* fee will be charged The Fellowship can accommodate post-graduates with practical courses in anæsthetics and courses in obstetrics, and can arrange for clinical assistantships at the Samaritan Hospital for Women Syllabuses of the Special Courses and copies of the programme of the General Course and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCVI —THE SURGICAL TREATMENT OF OSTEO-ARTHRITIS OF THE HIP-JOINT

When arthritis due to the specific organisms of tuberculosis and syphilis is eliminated from the wide field of chronic joint disease the remaining conditions fall into two great clinical groups (1) rheumatoid arthritis; and (2) osteo-arthritis Osteo-arthritis is mainly, if not exclusively, an affection of late middle life, which shows a predilection for the larger joints In this group the characteristic changes so frequently involve the *hip-joint* that osteo-arthritis of this articulation has come to be recognised as a definite clinical entity. Osteo-arthritis of the hip is ordinarily a monarticular affection—at least in its earlier phases—although bilateral involvement is by no means rare, the so-called sound hip being attacked some years later The morbid anatomy of this disease presents a familiar picture, the outstanding changes being essentially hypertrophic in type In the early stages the joint capsule becomes thickened, contracted, and adherent to the femoral neck From the articular surfaces the smooth cartilaginous covering is shed and the exposed bone becomes condensed and eburnated The sclerosis extends deeply and thus defeats Nature's efforts to bring about ankylosis Hypertrophic changes are best seen at the joint margins where a fibro-osseous lip is slowly built up on the acetabular rim Occasionally the osteophytic outgrowths may take the stalactite form, and project into the joint from the socket floor Later the femoral head expands and becomes mushroom-like, overhanging the squat foreshortened neck. The deforming process is usually progressive, but may halt and remain stationary for an indefinite time

Ætiology

It has long been recognised that trauma, infection, or metabolic disturbance may be concerned in the initiation of the deforming joint changes, but in many cases the causal relation of such factors is pure hypothesis Recent clinical observations suggest that in many hip-joints which become the site of osteo-arthritis structural defects have existed from the time of birth Calot believes that every osteo-arthritic hip is primarily a congenital subluxation Such a view is not yet accepted, but the frequent incidence of osteo-arthritis in hip-joints which show the stigmata of congenital subluxation is now widely recognised

Clinical Manifestations

The classical title *Morbus coxæ senilis*, as applied to osteo-arthritis of the hip, is misleading, for the affection is more especially familiar in individuals in the prime of life Indeed, the joint lesion may arise in comparatively young adults

Early Signs —The most important early symptom is *pain* experienced in the region of the hip, and often referred towards the knee along the distribution of the sciatic and anterior crural nerves (The combination of sciatic and anterior crural pain is especially characteristic) At first the range of mobility in the joint is little impaired, but careful testing will usually demonstrate some restriction in the extremes of abduction internal rotation, and flexion The patient himself is often aware of such limitation before the objective signs are well marked At this stage the radiographic changes may be barely appreciable

Later Signs —In typical cases the intractable "sciatica" is accompanied by a progressively increasing fixation of the joint, which ultimately assumes a position of adduction and flexion. The limitation of movement now becomes obvious even to the uninitiated clinical observer, and in a radiogram the deformation of the joint surfaces is easily recognised For a considerable time a good deal of the restriction of mobility is due to muscular spasm, as an examination under an anæsthetic will often show. True ankylosis is unknown; if it occurred the patient would be spared much of the distressing pain After years of suffering the pain tends to diminish in severity and often a state of comparative comfort is attained, although marked lameness and crippling exist

Surgical Treatment

Under ideal conditions surgical interference should rarely be necessary in osteo-arthritis of the hip-joint These conditions imply the recognition of the affection in its earliest phases, and the elimination of the underlying primary cause, whether this be trauma, infection or some specific metabolic disturbance Meanwhile, the irritable joint would be rested for a definite period, with absolute relief from weight-bearing Under such a régime the deforming changes would be checked, and almost perfect function conserved.

But in the present state of our knowledge concerning the pathogenesis of this disease ideal preventive therapeutics continue to be somewhat disappointing In actual practice we are repeatedly called upon to deal with osteo-arthritis of the hip in its mature stage, after long-continued medicinal, vaccine, and physiotherapeutic treatment have failed to prevent or abolish pain and disablement

In patients of suitable age and physique the question of the relief to be afforded by well-conceived surgical attack then becomes of considerable importance The surgical procedures which have established themselves as effective may be described under four headings. (1) manipulation under anæsthesia; (2) excision of capsule and osteophytes; (3) arthrodesis; and (4) reconstructive excision of the femoral head.

Manipulation —In the earlier stages of osteo-arthritis it is often possible to stretch the infiltrated capsule and break down the adhesions between it and the head and neck by a timely manipulation under an anæsthetic This manœuvre is eminently suitable for active and robust individuals who are concerned especially with an increasing limitation of mobility which interferes with their enjoyment of exercise and sport In manipulating such hip-joints particular attention is paid to the restoration of the movements of abduction and rotation The stretching should be carried out steadily, and the force used must be well within the limits of danger No untoward reaction should follow, and the increase in mobility thus obtained should be assiduously conserved by post-manipulative exercises

In patients judiciously selected the increased range of mobility is usually accompanied by lessened discomfort, and the full benefits of manipulation can be expected to last for several years But if, during this time the disease becomes arrested manipulation then is a curative and not merely a palliative procedure. It should be unnecessary to emphasise the fact that forcible manipulation is useless and dangerous in hip-joints with advanced deformation, and is also to be avoided in elderly and frail subjects

Excision of Joint Capsule and Osteophytic Outgrowths (Capsulectomy) —Procedures which fall into this class are based on the operation of "cheilotomy" or removal of the osteophytic lip of the acetabulum which was introduced independently by Brackett, De Courcy Wheeler, and Sampson Handley some years ago At one time it was assumed that the newly formed acetabular lip acted as the chief obstacle to free mobility of the joint More extended operative experience has not confirmed this view so that cheilotomy in its limited sense is no longer regarded as an adequate operation. Combined, however, with a free *excision* of the infiltrated and adherent joint *capsule*, the operation has a definite place in the treatment of osteo-arthritis of the hip in the earlier stages Its rationale is founded on the well-established fact that the earlier symptoms—viz limitation of mobility and pain—are due to the shortening and adherence of the thickened joint capsule The operation represents the alternative to manipulation pure and simple where, for mechanical reasons, the latter procedure is unlikely to produce the desired mobilisation

Arthrodesis—When the deformation changes are well advanced, the more drastic procedure of surgical fixation of the affected joint must be considered Arthrodesis of the hip has now been practised long enough for its merits and drawbacks to be appreciated It is quite certain that the majority of patients with well-marked osteo-arthritis are contented when the joint is completely ankylosed in a useful position and thereby becomes painless The production of sound ankylosis is, however, by no means an easy matter It is necessary to remove freely the eburnated bone-layers from both femoral and acetabular surfaces, an operation which may take a long time, and is often a fairly severe test of the endurance of the patient For robust patients of middle age arthrodesis may be regarded as a safe operation and, on the whole, the end-results are satisfactory both to the patient and the surgeon For its performance the hip-joint may be approached (*a*) by the postero-lateral route, after detachment of the great trochanter —a method which the writer favours—or (*b*) from the front by the Smith-Petersen incision

After denudation of the joint surfaces to expose cancellous bone the hip is brought into a position of moderate abduction and 30 degrees flexion This is maintained in a long plaster-of-Paris spica Six weeks later a short spica is applied and the patient is allowed to use crutches or may attempt partial weight-bearing in a Thomas caliper splint When firm fixation has occurred—as judged by clinical and radiographic tests—the plaster or walking splint is discarded In a certain number of cases true bony ankylosis fails to develop, but a degree of fixation something less than the ideal is often not unsatisfactory A few patients complain of backache after arthrodesis of the hip-joint, a symptom which points to the undue strain now borne by the lumbar spine and sacro-iliac joints

Reconstructive Excision of the Femoral Head—For many patients, and particularly those who are past middle age, it is desirable to attempt to produce a painless hip-joint and at the same time to retain some degree of motion The latter adds greatly to the comfort of the patient, not only in walking, but also in sitting With this end in view, the reconstructive excision operation has been evolved The technical details of my own operation[1] follow the lines of the reconstructive operation described and practised by Royal Whitman, of New York, for ununited fractures of the femoral neck (1921) and later applied in cases of arthritis deformans (1924) The mushroomed femoral head is freely excised and after the stump of the neck has been rounded off and smoothed by filing, it is thrust deeply into the acetabulum with the hip abducted The trochanter, previously detached to allow free access to the joint, is now attached to the femur at a considerably lower level This reconstructs a longer femoral neck, and ensures to the hip-joint the mechanical advantage of a better abductor leverage

Traction is applied to the limb with the hip in the abducted position, the patient being nursed either on an abduction frame or a Pearson fracture bed Active movements are begun at the end of a fortnight, and six weeks after the time of the operation a walking caliper splint is fitted

This operation is gaining in popularity amongst surgeons who are called upon to deal with osteo-arthritis of the hip-joint, and in properly selected cases the results are most gratifying Pain is almost invariably abolished and often a limited though useful range of mobility persists If there is any possibility of osteo-arthritic changes developing in the opposite hip-joint, reconstructive excision must be preferred to arthrodesis in patients of all ages

BISMUTH IN THE TREATMENT OF SYPHILIS

By Thomas Anwyl-Davies, M B , B S Lond , M R C S Eng
(*From the Venereal Diseases Department, St Thomas's Hospital, London*)

For the past five years bismuth has been employed as a therapeutic agent for combating syphilis, and varying results have been obtained by different workers In what follows I have endeavoured to summarise the knowledge that has been collected and to indicate how far my experiences in a large venereal clinic confirm and extend the conclusions of other workers

History

The idea of treating syphilis with bismuth was first entertained, in 1889, by Balzer,[1] who unfortunately discarded it on account of the severe toxic reactions obtained when the ammonium citrate salt was injected into dogs Sauton and Robert,[2] in 1916, examined the action of the tartrobismuthate on spirillosis gallinarum and, finding that "the tartrobismuthate of sodium exercises a bactericidal action on *Spirochæta gallinarum*," thought it might be useful in the treatment of syphilis Sazerac and Levaditi,[3] in 1921, following these experiments on animals, were the first to state that "the tartrobismuthate of potassium and sodium has a decided curative effect on experimental syphilis in rabbits" In the following year, after tests on man, they[4] stated that "bismuth is comparable to the best antisyphilitic remedies It seems to work more effectively than mercury, although in certain cases less rapidly than the more active arsenical drug" This was confirmed by Fournier and Guénot,[5] who treated 200 cases with bismuth and found that *Spirochæta pallida* disappeared rapidly and that the Wassermann reaction became negative in primary and secondary cases, although it was almost unaltered in late syphilitic disease

Mode of Action

The method by which bismuth attacks *S pallida* was reported on by Levaditi and Nicolau[6] Apparently, bismuth salts do not kill in vitro, even when mixed with blood or blood-serum, but if fresh cellular extract is added the solution immediately becomes active and is able to destroy the spirochætes Thus, Levaditi and Nicolau found that soluble bismuth salts mixed with rabbit's liver extract gave rise to a substance which kills trypanosomes and spirilla in vitro and gave good results in syphilis The bismuth solution was activated by all tissues of the rabbit and by the liver of other animals They consider that liver extract transforms the bismuth into a bismo-protein—"bismoxyl"—which is a toxalbumin, a derivative of the cell proteins This is precipitated from bismuth liver extract on standing and is non-dialysable Bismoxyl prepared from brain extract is said to be 1000 times more powerful than that prepared from muscle Levaditi, Gérard, and Manin[7] think that minute traces of bismuth, acting as a catalytic agent, cause a chemical immunity They consider this immunity, which is prolonged, to be characteristic of bismuth and that no other antisyphilitic remedy is to be compared with it in this way Kolle[8] experimented with 26 rabbits inoculated with syphilis Those injected with insoluble bismuth did not develop chancres even after 109 days, but infection took place in those animals which received the easily absorbed soluble preparations He does not, however, consider this a proof that a deposit of insoluble bismuth in the tissues is a prophylactic against syphilis

Valuable research by Kolle and Evers[9] suggests that bismuth acts by inhibiting the reaction of the tissues rather than by inhibiting *S pallida* A bismuth suspension was injected subcutaneously into the ears of rabbits and four weeks later these were inoculated with *S pallida* No primary lesion or generalised syphilitic infection occurred until the bismuth deposit was removed two or three months later by amputating the rabbits ears When this was done, typical chancres developed and the usual train of syphilitic signs ensued without a fresh spirochætal inoculation Then they showed that in rabbits which had been inoculated with *S pallida*, but in which no chancre had developed owing to the presence of the depôt of bismuth, the popliteal lymph glands contained *S pallida* Thus, this organism had not been prevented by the bismuth from travelling into the tissues They made an emulsion from the popliteal lymphatic glands of rabbits in which the syphilitic infection had not developed owing to the presence of the bismuth deposit and demonstrated that other animals could be infected by inoculating them with this emulsion In one experiment infection took place and the chancre formed in a rabbit which had been inoculated with the lymphatic emulsion from an apparently immune rabbit (which had been inoculated with the lymphatic gland emulsion from another apparently immune rabbit which had not reacted to inoculation owing to the bismuth deposit)

Thus, the popliteal lymphatic glands of such apparently resistant rabbits are infectious, and it seems as though the bismuth in some way—possibly by some tissue reaction—merely *inhibits* the disease instead of having a direct curative action on the infection These experiments suggest that the therapeutic effect of bismuth may not be as satisfactory or as permanent as one might desire

Absorption and Elimination

The human system may be strongly impregnated with bismuth Mme A. L Draganesco [10] demonstrated that *sodium potassium* bismuth tartrate injected intramuscularly caused the deposition of bismuth in the large intestine, kidneys, spleen, salivary glands, brain, and liver (diminishing in amount in that order) and that the quantities of bismuth found in the different organs were not related to the amounts of blood in those organs A histochemical method for the detection of bismuth in the tissues was devised by Levaditi, Nicolau, Salgue, and Schoen,[11] by which 0 001 mg could be estimated in the tissues or body fluids Their experiments showed that the kidney, lung, and spleen held the largest amounts of bismuth, but that syphilitic lesions contained infinitesimal quantities of bismuth, there being no accumulation of the metal at the site of the destruction of the spirochætes An electrometric method was used by Christiansen Hevesy, and Lomholt [12] to determine the amount of bismuth in the various body tissues A mixture of the bismuth salt and its radio-active isotrope was injected into the animal The radio-activity of the organs was then measured electrometrically for the content of the radio-active isotrope, from which the amount of bismuth present was calculated The heart, lungs, and liver were found to contain only a small quantity of bismuth, while the kidneys held twice the amount found in the liver

Levaditi,[13] experimenting on rabbits with various bismuth compounds found that when administered intramuscularly they are absorbed according to their solubility, the insoluble preparations being absorbed slowly while the soluble compounds are assimilated rapidly and eliminated so quickly that kidney lesions are caused This toxic action on the kidneys was never found in animals even after very large doses, when the insoluble bismuth salts had been administered The insoluble bismuth salts and metallic bismuth are not absorbed unless they are previously rendered soluble by leucocytic proteolysis This gives rise to proteo-bismuth compounds which travel throughout the body and are eliminated chiefly through the kidney Phagocytosis occurring in the muscles helps to form a bismuth depôt there, which is greater in the case of the insoluble bismuth salts The depot supplies the body with relatively minute quantities of an organo-metallic salt, containing hidden bismuth, which is sufficient for the destruction of *S. pallida*

The routes of elimination are the same as for mercury. Bismuth has been demonstrated in the urine fæces, saliva, blood, bile, sweat, and cerebro-spinal fluid All authorities do not agree that bismuth reaches the cerebro-spinal fluid, but it has been found there by Schuller [14] within 96 hours of injection This observation is probably correct and would explain the good results obtained when bismuth is used in the treatment of syphilis of the nervous system

Christiansen Hevesy, and Lomholt [12] found that the amount of bismuth eliminated by the kidneys is double that excreted by the large intestine Elimination is more rapid after intravenous injections than after the intramuscular route, and more rapid with the soluble salts than with the insoluble preparations Gruhzit [15] found that after a single dose of bismuth salicylate the maximum elimination occurred in about five days Of the total amount of bismuth excreted, 77 to 92 per cent was found in the urine, and from 8 to 23 per cent in the fæces Fournier and Guénot [16] found bismuth in the urine 18 to 20 hours after the initial injection It may be detected in the urine for a considerable time afterwards

Interesting experiments on rabbits by Leonard and O'Brien,[17] who took into account the exact bismuth-content of the potassium bismuth tartrate used, showed that the tolerated dose of the insoluble potassium bismuth tartrate (150 mg per kg) is greater than that of the soluble sodium potassium bismuth tartrate (100 mg per kg) The rate of excretion of the soluble salt is also higher, falling off progressively before death, whereas the rate of excretion of the insoluble tartrate does not fall off, being fairly steady from day to day. With both drugs they found a lowered rate of excretion, and when the dose was increased the total excretion was lessened, corresponding with the extent of the damage to the kidney tubules

Some important experiments by Leonard [18] have proved that the dose of metallic bismuth which can be tolerated by rabbits when injected intramuscularly is 400 mg per kg , this is greatly in its favour compared with the insoluble potassium bismuth tartrate, the tolerated dose of which is only 150 mg per kg He also found that metallic bismuth has a range of nephrotoxicity extending from below 85 mg per kg. to 500 mg per kg , the lethal dose In comparison, the nephrotoxic range for the insoluble potassium bismuth tartrate is very small—only from 120 to 180 mg per kg , which indicates that it has a much sharper effect on the kidneys than has metallic bismuth

Groehl and Myers [19] claim that there is increased urinary excretion of arsenic in man after the use of bismuth thiosulphate Leonard [20] confirmed this and considered that the detoxicant action of thiosulphates upon heavy metals may be explained as a mobilisation of insoluble depôts which are producing local toxic lesions in the skin or mucous membranes The metal, when thus mobilised, may be more toxic in its acute effects on the kidney, but human therapeutic doses rarely reach a concentration dangerous to normal kidneys even when thus mobilised Sodium bismuth thiosulphate may therefore be a useful alternative or adjuvant treatment in certain cases of arsenical or mercurial intolerance where albuminuria is not a symptom

Choice of Preparation

Bismuth compounds may be divided into three large groups . (*a*) insoluble preparations suspended in water , (*b*) insoluble preparations suspended in oil · and (*c*) soluble preparations All these drugs are obtainable in great variety under trade names

Insoluble Preparations Suspended in Water —Those mostly in use are bismuth hydroxide, bismuth oxychloride, metallic bismuth, and sodium potassium bismuth tartrate These compounds are slightly painful when administered alone One preparation of bismuth oxychloride, however, contains chloretone, which acts as an analgesic and a preservative, whilst another preparation on the market is a very fine suspension of precipitated metallic bismuth in an isotonic glucose solution; hence these two preparations are practically painless. The actual bismuth-content of the first three preparations is high, but actual figures are not quoted.

Insoluble Preparations Suspended in Oil.—The chief are sodium potassium bismuth tartrate, metallic bismuth, bismuth oxide, iodobismuthate of quinine, and bismuth salicylate. These preparations are not so painful as the insoluble drugs in an aqueous solution and there is no local reaction at the site of injection. Their actual bismuth-content is not as high as that of the preparations in the first group.

Soluble Preparations.—The most important of these is the soluble sodium potassium bismuth tartrate, which is made by taking up the insoluble salt of the same name in just sufficient alkali to make a clear solution. This was chiefly used by Jeanselme, Chevallier, Pomaret, Blamontier, and Joannon.[21] The soluble salts, although they give results analogous to those obtained with the insoluble preparations, have passed into disfavour because of the intense local reaction and the severe pain which follow their injection, and on account of their greater toxicity. The bismuth-content is low.

The different preparations have been used by various observers for definite reasons. Thus, the sodium potassium bismuth tartrate was chosen originally by Sazerac and Levaditi[22] because of its low toxicity. At first it was used in an aqueous solution rendered alkaline,[23] but this was painful, and later it was superseded by a suspension of the salt in oil. After this they reported[21] that equally favourable results were obtained when metallic bismuth was used in an oily suspension. The first results of Fournier and Guénot[25] were obtained by administration of sodium potassium bismuth tartrate in an oily suspension, but later they[26] used metallic bismuth in a 10 per cent. isotonic suspension, which they recommended highly. Lomholt[27] found that although the oily compounds were almost painless, they were absorbed much more slowly than aqueous preparations. The latter were absorbed and eliminated very rapidly. He considers the most satisfactory preparation to be a suspension of bismuth hydroxide made up in 10 per cent. glycerine to ensure the stability of the suspension. All compounds of bismuth are probably reduced to metallic bismuth before "bismoxyl" is formed. Burke,[28] therefore, considers bismoxyl itself or metallic bismuth to be the most scientific form to use. He finds that the results obtained with metallic bismuth suspended in an isotonic glucose solution are more satisfactory than those with any other preparation on account of its painlessness and satisfactory rate of absorption.

In addition to the general preparations of bismuth mentioned above, a very large number of compounds have been used of which it is only possible to quote a few. Thus Barthelemy[29] found that the bismuth oxides, being heavy and coarsely granular, tend to produce abscesses. I have only seen one abscess in several thousand injections of bismuth compounds; in this particular case several ounces of pus were removed from a feeble old lady who had received 0·3 g. of bismuth oxychloride. The insoluble iodoquinate is weak in action on account of its low bismuth content and slow absorption but the tonic action of the quinine and iodine may be an advantage in some cases.

Observations in the St. Thomas's Hospital venereal department showed that the soluble tartrobismuthate caused the spirochætes to disappear sooner than did most of the preparations of bismuth tested, but this preparation was discarded because of the intense pain caused by its injection. Possibly soluble preparations which have lately been ousted by the comparatively painless insoluble compounds may return to favour owing to their more powerful spirochæticidal action if a painless method of administration can be found.

In general the soluble drugs appear to be absorbed and eliminated too rapidly, while the preparations in oil seem to be absorbed too slowly. Apparently the insoluble preparations in water are absorbed at a satisfactory rate. In France the sodium potassium bismuth tartrate and the iodobismuthate of quinine are especially popular. In America the tartrobismuthate, the salicylate, the hydroxide, and the iodoquinate are mostly in use, the tartrobismuthate appearing to be the most favoured.

A general consideration of all these facts, and my own experience, indicate that the most satisfactory preparation is an insoluble salt of bismuth, or metallic bismuth itself, suspended in an aqueous medium with as high a bismuth-content as possible.

Administration

Method.—Although Lacapère[30] has used colloidal bismuth intravenously, this method is contraindicated, as Sazerac and Levaditi have shown that bismuth preparations are ten times more toxic when injected intravenously than intramuscularly. Klauder[31] has demonstrated that inunctions are almost inactive. For both soluble and insoluble compounds the intramuscular route is mostly in vogue and is quoted by all authorities, but in the literature of the subject no special mention is made of the deep subcutaneous injection which in my opinion, is the best. Apart from the compound used, any intramuscular injection is inclined to cause stiffness, cramp of the muscles, and pain down the legs, all of which are obviated by a subcutaneous injection. This is an important point, as the chief advantage in using bismuth instead of mercury is on account of its painlessness. One clinic in England is known to the writer where bismuth oxychloride was given up on account of the pain caused by its use intramuscularly. The same preparation can be given deep subcutaneously without any inconvenience, except for the initial discomfort, which lasts over 30 seconds while the injection is being administered. My experience is that the bismuth hydroxide, the oxychloride, and metallic bismuth are equally effective and should preferably be administered in this way. By this method also the possibility of an inadvertent injection of a bismuth compound suspension into a vein is greatly lessened, this being much more likely to occur with an intramuscular injection than with a deep subcutaneous injection. Practitioners should be warned that if the injection is placed just beneath or too near the skin instead of deep to the subcutaneous fat, pain and induration are likely to follow. This is easily avoided by pinching up the skin and subcutaneous tissues between the thumb and forefinger and injecting the solution on to the fascia covering the muscles beneath. The needle should be inserted separately from the syringe so that, if a blood-vessel is tapped, the blood is seen to escape from the needle before the syringe is attached. When this happens the needle must be partly withdrawn and reinserted *in another position*. That the danger of injecting bismuth into the blood stream accidentally while *giving an intramuscular injection* is a very real one is illustrated by the fatal case reported by Dr. C. F. Chenoy.* An injection was inadvertently given into a vein of the gluteal region, and was followed almost immediately by thoracic pain and cramp in the legs together with perspiration and suffocation. The patient then became unconscious, with dyspnœa and paralysis of both legs, and died within two hours of the injection.

The site for an intramuscular injection has to be chosen very carefully in the upper and outer quadrant of the gluteal region, but a deep subcutaneous injection can be given at almost any spot on the buttock, a distinct advantage when a large series of injections are necessary. Colonel L. W. Harrison[32] is accustomed to inject both the bismuth compound and an arsenical preparation in this way through the same needle into different sites without making a second puncture of the skin

---

* Indian Medical Gazette, May, 1926.

Dosage—It is the general practice to give injections of 0 2 to 0 3 g once or twice a week until signs of intolerance appear Generally a total of 2 to 4 g is given in a series of 10 to 12 injections

Therapeutic Results

The reports and findings of workers in various countries are very diverse, and many observers have been disappointed by the therapeutic action of bismuth since Fournier and Guénot[5] published their brilliant results in 1922

Effect on Wassermann Reaction—Sufficient time has not elapsed since the drug came into use to form any definite conclusions as to the curative value of bismuth and its permanent effect on the Wassermann reaction Fournier and Guénot[5] reported that the Wassermann reaction in primary cases with a positive reaction became negative after one course of bismuth in 100 per cent of cases Ahlswede and Busch,[33] after three years' experience with bismuth, consider that it has a lasting and powerful effect on the blood reaction Smith and Foster[34] state that the use of bismuth did not reduce the Wassermann reaction of either the blood or cerebro-spinal fluid in cases of syphilis of the nervous system, and that it had no marked influence on the Wassermann reaction in cases of tabes and general paresis although the symptoms were relieved McCafferty[35] reported a series of 25 Wassermann-fast cases in which the positive reaction became negative or was diminished in 64 per cent of the cases by one course of bismuth Marshall[36] found that 41 per cent of Wassermann-fast cases became negative, and the blood reaction was reduced in 18 per cent of cases Sidlick,[37] of Philadelphia, will not admit that Wassermann-fast cases become negative under bismuth The experience of Dr P A Clements[38] at St Thomas's Hospital venereal department is that, in cases of late syphilitic disease and in Wassermann-fast cases, bismuth does not cause a positive blood reaction to become negative

At St Thomas's Hospital venereal department[39] the Wassermann reaction results from a series of acute syphilitic cases which were treated with arsenobenzol and mercury were compared with those from a similar series of cases treated with arsenobenzol and bismuth The cases included in both series were primary lesions with a negative or a positive Wassermann reaction, and secondary cases with a roseolar or a papular rash, which had received not less than 5 g of "914" during the first course of injections, plus not less than 8 gr of mercury, or 2 g (average 3 6 g) of bismuth The results were judged by the Wassermann reaction of the blood-serum obtained within two months of the completion of the course The percentages were calculated from a series of 240 cases treated with mercury and arsenobenzol, and 185 cases treated with bismuth and arsenobenzol, all of which satisfied the above conditions The percentage of completely negative Wassermann results was 81 7 in the mercury series against 77 3 in the bismuth series The incompletely negative (±) Wassermann reactions (indicating that the continuation of treatment is essential) was 6 7 per cent in the mercury series, against the high percentage of 14 1 in the bismuth series Thus, it is observed that, at the end of the first course, the percentage of completely negative Wassermann reactions is higher in cases treated with mercury, while borderline results (incompletely negative) were commoner in the bismuth series

Disappearance of S pallida—At St Thomas's Hospital venereal department it has been found that spirochætes disappear from the early syphilitic lesions much more slowly after bismuth than after arsenical preparations—viz , in five or six days The organism can generally be found after the second injection, but not after the third (although this occasionally occurs), when a dose of 0 3 g is given three times in a week Gruhzit,[14] of Detroit on the other hand, obtained absolute cures in all his infected rabbits He found that bismuth salicylate in doses of 5 mg per kg. killed *S pallida* in 48 hours

Clinical Effect on Primary and Secondary Lesions—These disappear under bismuth alone, perhaps quicker than with mercury, but not so quickly as with arsenobenzol The writer has noticed that secondary lesions of the mouth and tongue respond particularly well to bismuth Chenoy[40] confirms this, as he obtained the best results in cases of mucous patches of the mouth, cheek, or palate In treating 200 cases of secondary syphilis he found that the lesions generally cleared up after the administration of 1 g of metallic bismuth. Dennie[41] says that in his experience bismuth has been unsuccessful in controlling cases of recurrent early syphilis, cutaneous secondary lesions having followed soon after an initial course of treatment

That bismuth has a definite spirochæticidal action is supported clinically by the frequent occurrence of the Jarisch-Herxheimer reaction after its use Ehlers and Sloth[42] noted 20 per cent of Herxheimer reactions in cases of secondary syphilis treated with bismuth at Copenhagen, and other cases have been reported by Jeanselme and Blamontier [43]

Tertiary Lesions—In the later stages of syphilis symptoms often intractable to arsenic and mercury have been relieved by a comparatively few injections of bismuth I have repeatedly noticed that cases of gummatous ulceration and of tibial periostitis, which have relapsed or refused to heal under arsenic or mercury, have responded favourably to bismuth Parnell,[44] at Haslar, found that bismuth has "especially beneficial effects upon cases of glossitis and chronic leukoplakia of the mouth, and can be given safely to cases of arsenical jaundice " Chenoy[40] remarks that, in tertiary lesions of the mouth and tongue, the results were better with bismuth than those of similar cases treated with arsenic In my experience bismuth seems particularly effective in tertiary cases with lesions of or in the mouth Perhaps this is because they are bathed in the patient's bismuth-excreting saliva A pregnant woman, who had been on milk and soft diet for a fortnight on account of the pain from a large gumma in the right side of the tongue and severe ulceration along the right margin and tip of the tongue, was able to eat normal food, and the pain had gone 24 hours after a deep subcutaneous injection of 0 3 g of bismuth oxychloride No other drugs or form of treatment was given, and no previous antisyphilitic treatment had been administered Three days after the injection the ulceration was only just perceptible, and the tongue had become normal in size

Neurosyphilis—Bismuth appears to be more valuable than mercury in the amelioration of tabetic symptoms Lightning pains, gastric crises, and incontinence of urine are relieved more rapidly with injections of bismuth than with mercury, and sometimes the relief secured is remarkable Marie and Fourcade,[45] in Paris, produced a Herxheimer reaction with bismuth, provoking lightning pains in a tabetic case The results in cases of general paralysis are very poor Smith and Foster[34] found that the symptoms of cerebro-spinal syphilis are relieved One case of syphilitic meningitis recovered rapidly and there had been no return of symptoms 11 months later They consider bismuth of value especially in relieving the subjective symptoms of syphilis of the nervous system, while in tabes and general paralysis it gives as good results as does any other form of treatment

Advanced Organic Disease—Musser[46] concludes that bismuth in certain selected cases of advanced organic disease has a greater value than salvarsan, especially in cases of cardiovascular syphilis and nephritis

Syphilis in Conjunction with Pulmonary Tuberculosis In collaboration with Dr G T Hebert of the tuberculosis department of St Thomas's Hospital, the writer has found that arsenobenzol, even when small doses are given intramuscularly, is inimical to patients suffering from pulmonary tuberculosis The disease in the lungs seems to progress rapidly if arsenobenzol is administered, but bismuth seems to have no deleterious effects and is not contra-indicated in these cases

Poor Results —Cases occur in which bismuth seems to have little or no therapeutic action Seven cases of recurrence after bismuth are reported by Simon and Bralez,[47] who consider that at least 2 g of bismuth should be given to prevent relapse, although in one of their cases the disease recurred within a month of receiving 9 5 g of bismuth Lortat-Jacob reported a case of secondary syphilis which developed a mucous plaque full of *S pallida* after receiving seven injections of bismuth, totalling 1 12 g of metallic bismuth, but recovered with mercury inunctions Burke's[28] opinion is that mercury has become obsolete in the treatment of syphilis, and that bismuth falls little short of arsenobenzol in its effect upon superficial and visceral manifestations and upon the serological reactions of the blood and cerebro-spinal fluid. Milian[48] expresses the relative therapeutic values of the antisyphilitic drugs as follows arsenobenzol 10, bismuth 7, and mercury 4 Personally I have no evidence for such a high curative figure for bismuth and consider bismuth and mercury more nearly equal, mercury possibly being as effective as bismuth—if not more effective when skilfully administered Bismuth, however, though possibly not so powerful as mercury, is more convenient to use

(In the concluding portion of this article, which will appear later, Dr Anwyl-Davies deals with intolerance to bismuth, indications for its preference to mercury, and concludes with references to current literature)

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Unrest among Poor-law Authorities

THERE are many signs of unrest among the parish councils as the result of Lord Constable's decision that emergency relief paid to miners' dependents during the strike was illegal In one area the parish council has received a number of refusals to pay the rate involved, and resolutions have been passed suggesting that the Government should refund to the parish councils the amounts illegally incurred on the central initiative—all this notwithstanding the announcement that the position will be dealt with by legislation In some areas the parish rates have risen to a point where recovery may be difficult or impossible, and the stoppage has undoubtedly raised some very difficult questions of local government finance The parallel conditions in England are equally difficult, although the law is different in some essential points The early part of the Parliamentary session promises some interesting discussions

Scottish Hospitals and the Coal Stoppage

It is now possible to see to what extent the coal stoppage affected two large hospitals—namely, the Edinburgh and Glasgow Royal Infirmaries In Edinburgh the miners' contributions showed a falling away to the extent of £4655 In Glasgow the loss amounted to about £6000 and the bill for coal showed a rise of some £5000, thus the stoppage directly cost Glasgow Royal Infirmary £11,000, and doubtless other hospitals suffered in proportion In both cities, however, the general financial position of the Royal Infirmaries is satisfactory In Edinburgh the League of Subscribers, instituted in 1919, has been very successful in maintaining or even in increasing the contributions The patients treated in 1926 numbered 17,024, as against 15,755 in 1925 The daily average remained as before, 905, for the average stay in hospital fell from 20 6 days to 19 03 The cost per occupied bed was £143 10*s* 9*d*, an increase of £2 7*s* 6*d* on the figure for 1925

Edinburgh Royal Infirmary and the Simpson Memorial

It is announced that the Royal Maternity and Simpson Memorial Hospital is to be amalgamated with the Royal Infirmary For many years the need for a larger maternity hospital has been discussed, and at first it was proposed that an appeal should be made for a new or extended maternity hospital to work as an independent body It was all along felt that the great name of Simpson deserved to be perpetuated in this way, and I have no doubt that in the arrangements now in prospect that name will not be forgotten But the advantages of functional unity were admitted on every hand from the beginning, and when it was clear that the maternity and gynæcological services of the infirmary must be improved, some working arrangement had to be made if the medical school was not to suffer and if the functions of two rival organisations were not to overlap Under the able and generous chairmanship of Dr Goodall Nasmyth, the Simpson Memorial has undergone many improvements, the new Ballantyne Memorial Antenatal Department is acknowledged to be a model of its kind and worthy of the life-time of propaganda which its name commemorates But circumstances have arisen to make the amalgamation of the Royal Infirmary and the Simpson Memorial both desirable and practical It is likely that a portion of the Watson's College site will be used for the erection of a modern gynæcological and maternity hospital, this whole department will then be an integral part of the Edinburgh Medical School, and the arrangement is certain to give general satisfaction

IRELAND

(FROM OUR OWN CORRESPONDENT)

Statistics of the Irish Free State

THE most notable fact in the 1925 report of the Registrar-General is the high figure for emigration—30,302, compared with 19,077 for 1924 As usual the great majority—26,546—of the emigrants went to the United States of America Marriages numbered 13,820, which is equivalent to a rate of 4 63 per 1000 of the estimated population and is 1002 below the figure for 1924 Births numbered 62,069 (31,818 boys, 30,251 girls), which is equivalent to 20 8 per 1000, the rate in Northern Ireland was 22, in England and Wales 18 3, and in Scotland 21 3 The total number of deaths was 43 650, and the death-rate (14 2 per 1000) was 0 41 below that of 1924 and 1 30 below the average for ten years The death-rates in other countries were Northern Ireland, 15 74, England and Wales, 12 16, and Scotland, 13 39 The death-rate from all forms of tuberculous disease was 1 57 per 1000, as compared with Northern Ireland, 1 67, England and Wales, 1 04, and Scotland, 1 10 During the past two years the mortality in the Free State from this cause has been rising In 1925 the death-rate was highest in Dublin Borough (2 31), Cork City (2 22), and Tipperary S R (2 02) The lowest rates were in Roscommon (0 78), Longford (1 13), Mayo and Sligo (1 16) Deaths from cancer numbered 2801, a decrease of 12 as compared with 1924 There was a distinctly upward tendency in the mortality from cancer in the years 1923 and 1924 The number for 1923 gave an increase of 8 per cent on 1922, and 1924 gave a further increase of 6 per cent on 1923 The mortality from cancer in An Saorstat during the five years 1921–25 is given as 0 9 per 1000 A total of 1171 deaths were registered as due to influenza, compared with 2073 in 1924 Of deaths from all causes 14 6 per cent occurred among children under 5 years 45 7 per cent amongst persons aged 65 or over, and 37 3 per cent in persons of 70 or over The mortality amongst infants under one year was 68 per 1000 births, compared with an average of 77 for the ten years 1915–24 In Northern Ireland the infant mortality was 86 per 1000 births, in England and Wales, 75; and in Scotland, 91.

Enforcement of Vaccination

The Department of Local Government and Public Health has been for some time impressing on the health authorities of the county and town of Wexford the necessity for enforcing the Vaccination Acts, but little has so far been done. According to recent reports there are 2653 vaccination defaulters in the town, or nearly one-quarter of the total population. In the county there are some six or seven thousand defaulters. Despairing of obtaining any result by persuasion, the Department has at length taken steps to compel the Wexford Corporation to discharge its responsibilities. A conditional order, directed to the mayor and the other members of the corporation, has been granted by the High Court. The order directs the mayor and the other members to enforce the Vaccination Acts in this district, and warns them that unless they do so within ten days of the service of the order, application will be made to charge them with the costs of the court proceedings. As regards the county health authority the Minister has not as yet taken any drastic steps. He has, however, directed a letter to be sent to the effect that neglect of vaccination shows a very lamentable want of public spirit and poor citizenship on the part of the Board of Health and Public Assistance. He is not prepared to acquiesce in the disregard of the provision of the Vaccination Acts. A serious outbreak of small-pox at present exists in a neighbouring country, which renders suitable precautions all the more essential.

BERLIN

(FROM OUR OWN CORRESPONDENT.)

The Campaign against Practice by the Unqualified

BEFORE a combined meeting of the Berlin Arzte-Bund and the Society of Berlin Lawyers Dr Ebermayer, retired director of public prosecutions in the Supreme Court of Leipzig, recently read a paper on the duty of the Government to protect the public against the consequences of unqualified practice and on the legislation at present in force. He stated that since the Trades Act of 1869 unqualified practice has spread in a way never anticipated by the authors of the Act, amongst whom was the late Prof Virchow, then a member of the Reichstag. Since the passage of the Act anyone has been allowed to attend patients provided he does not use the title of *Arzt* (doctor) or a similar one. Dr Ebermayer described as quacks both the man who attends patients without being duly qualified, and the man who advertises secret remedies. The number of unqualified practitioners rose in Berlin from 28 in 1879 to 1349 in 1903 and by 1925 there were 5648 unqualified doctors in Prussia alone. The causes of the increase are (1) the bad financial condition of the population, which induces patients to consult unqualified persons because they believe their advice to be *cheaper*; and (2) the prevalence of mysticism and the systematic campaign against so-called official medicine carried on by the associations of quacks. Several German Acts however, contain provisions against unqualified practice; under the Workmen's Insurance Act and the Vaccination Act for instance, medical practitioners are only recognised as such if they have a qualification. Unqualified persons are also liable to prosecution under the Trades Act, the Unfair Competition Act and the Criminal Code. The provision of the Trades Act that only a qualified medical man may call himself *Arzt* is often violated by unqualified persons who use titles with a similar sound. The Unfair Competition Act may be brought into force against anybody who in advertising a secret medicine alleges that it cures ailments in a quicker and surer manner than other remedies. The Criminal Act may apply to an unqualified person who has caused death or bodily injury by neglect, but prosecution on this charge seldom leads to punishment as the prosecutor must prove that the defendant has failed to use the care which could be expected of him in view of his training. Dr Ebermayer concluded that as the present legislation is unsuitable, unqualified practice ought to be made a criminal offence by a new Act, which should prohibit the attendance of unqualified persons on any patients, except those requiring first-aid. Such a prohibition, he considers would be neither ineffective nor superfluous, as was alleged in the debates on the Bill of 1869. If complete prohibition has no chance of being enacted by the present Parliament, the absolute freedom to practise which is now enjoyed by quacks must at least be restricted.

The Arrangement of Medical Study.

The regulations of 1924 concerning the State medical examination have proved satisfactory neither to medical students nor to examining boards. At the time when the new regulations came into force, the financial condition of Germany was such that the medical curriculum could not be extended on account of expense, although the regulations included more branches of medicine than were formerly recognised. The Home Office has been considering revision of medical education and the State examination, and the medical faculties have been invited to make proposals. In order to allow students and the profession in general to give their opinions the publishers of the *Deutsche Medizinische Wochenschrift* have opened a competition for an article on the best arrangement of medical studies. Those entitled to take part in the contest are the subscribers to the journal (other than members of medical faculties and of examining boards), and medical students who have already completed the ninth or tenth term of their curriculum. The publishers reserve the right to publish the prize essay and to send others to the Home Office for consideration.

Deafness in School-children

Prof Gustav Bruhl, aurist to the Berlin School Board recently stated that 72,000 children in Berlin schools suffer from affections of the ear, and that 7250 of them are hard of hearing, 10 per cent of these being almost deaf. The city has only six special schools where 410 deaf children are educated—an accommodation obviously far too small. It seems practically impossible to have all the hundreds of thousands of Berlin school-children examined by aurists for not even the regulation that every child who is hard of hearing shall be shown to the municipal aurist has so far been complied with, many of the municipal schools not having sent a single child for examination. It is true that children often conceal their disability by following with their eyes the lip-movements of their teachers. Prof Brühl is of opinion that every child who makes no progress in his work should be examined by an aurist since deafness is so often the cause of inefficiency. Half the deaf children suffer from double chronic otorrhœa. Twenty per cent of them might be cured by adequate treatment, but this is often hindered by the indolence of the parents.

Hospital Accommodation in Berlin

The Berlin municipal hospitals have a total of 13 875 beds, 400 of which have been added during the past year. By far the biggest is the Virchow Hospital with 2517 beds; then come the Neukölln with 1086, the Friedrichshain with 1065 and the West End with 1030 beds. Of social hospitals there is the Children's Hospital with 440 beds an infants' hospital in Weissensee with 80 beds a maternity hospital with 270 beds and sanatoria for tuberculous patients in Charlottenburg Sommerfeld, and Hasenhaise with 350 beds each. With the construction of new wards and the purchase of private hospitals the number of beds in the municipal hospitals will next year be about 15 000. Besides the municipal hospitals there is the Charite Hospital, belonging to the State, and some university clinics having together 2000 beds.

There are infirmaries, with 700 beds, belonging to sick-clubs, and a number of private hospitals with a total of 5300 beds for the most part belonging to religious bodies Altogether 21,400 beds are available for the four million inhabitants of Berlin—i e , 5 35 beds for every 1000 inhabitants For incurable cases there are 7000 beds, and accommodation for 11,000 insane persons is at the disposal of the municipal authorities

Success of the Dusseldorf Exhibition

The great exhibition of hygiene, called *Gesolei*, which was held at Dusseldorf last year, was visited by 7,500,000 visitors and closed without a deficit This result was principally due to the excellent organisation of the exhibition for which Prof A Schlossmann, the well-known pædiatrist, was largely responsible, being chairman of the committee

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

Health of Undergraduates

THE American Student Health Association, which is composed of physicians attached to the leading colleges and universities, devoted its recent meeting largely to the subject of periodic medical examinations Comparatively few universities have felt justified in making the large outlay of labour and money involved in a thorough examination of all students each year Such examinations, however, are conducted at Yale, Cornell, the College of the City of New York, and Antioch College, whilst in two of the larger universities—Columbia and Minnesota—the examinations have been made on medical students only At Minnesota a questionnaire at the end of the year showed that more than half of the students had recognised benefit from the examination, whether by the discovery of physical defects previously unknown to them, the recognition of the importance of defects previously disregarded, or the removal of unnecessary worry about some impairment real or imaginary Eighty-eight per cent of the senior medical students approved of the examinations The chief criticisms offered were that the examination should be more comprehensive and that stereoscopic radiographs of the chest ought to be included in the routine Dr H. S. Diehl, director of the student health service in this university, said that he had come to regard the outlay necessary for these examinations as fully justified

In a presidential address Dr Thomas A. Storey stated that since September, 1906, the College of the City of New York has given required health examinations to more than 35,000 students every half-year during their undergraduate enrolment This should have made a definite impression on the citizenry of New York, for many leading citizens are now interested in preventive medicine and in being thoroughly examined by their physicians both as a preventive measure and when they are ill The college graduate, however, has not always found it easy to secure the services of doctors who exercise the thoroughness so desirable from the educational as well as the preventive viewpoint Doctors have examined with stethoscopes applied to the clothing or have discountenanced the idea of an examination at all when the applicant is not consciously in ill-health Dr Storey communicated with the deans of all the Class A medical schools in the country in an attempt to learn how reliable physicians might be recognised The deans agreed that such recognition is extremely difficult A few declined to answer the question, but many suggestions were made as to how a college graduate may safely select his health examiner The physician should be a graduate of a Class A medical school, he should have been an intern in a hospital approved by the American Medical Association, and he should be a member of the State Medical Association The medical directory may be consulted, but specialists should be avoided The superintendent of the local hospital may be consulted, or the secretary of the county medical society, or the local health officer Perhaps the best suggestion is that the students should be so educated in thoroughness and in the scientific method that they will be able to recognise slipshod methods at sight

Function of the Suprarenal Cortex

The eighty-third annual meeting of the American Association for the Advancement of Science has just been held in Philadelphia Prof W W Swingle, of the University of Iowa, gave an account of his research into the functional significance of the suprarenal cortex Working with cats he was able to show that if the medulla of one adrenal gland is curetted and the second gland is totally extirpated at a later operation, the animals survive, whereas, if both glands are totally extirpated the animals die in 40 to 60 hours, surviving only exceptionally for 100 hours Two hundred animals with cortical remnants survived for as long as 6–8 months, after which they were sacrificed in order to prove by autopsy that no medullary tissue remained Accessory glands were found in only five cases, and in four of these there was no medulla in the accessory gland Bilateral total removal results in a rapid rise of phosphorus in the serum , this is not seen as long as any cortex remains The protein-urea and non-protein nitrogen are also increased, and respiration becomes considerably quicker and deeper The animal passes rapidly into a lethargic condition and thence to coma Coincidently with these changes, the tension of carbon dioxide drops, and the pH concentration, though it is held constant for some time by the increased respiration, eventually falls In the absence of suprarenal cortex the kidney apparently fails to remove the acid products of metabolism. No constant pathological lesions were found in the kidneys at autopsy

The Services.

ROYAL ARMY MEDICAL CORPS

Maj -Gen O L Robinson, K H P , late R A M C , having attained the age-limit for retirement, retires on ret pay

Lt -Col L N Lloyd, from R A M C , to be Col

Capt J E Foley retires, receiving a gratuity

ARMY DENTAL CORPS

Temp Lt I A. Barlow, Dental Surg , Gen List, to be Lt.

SUPPLEMENTARY RESERVE OF OFFICERS

Capt W S Dawson resigns his commn , and retains the rank of Capt

TERRITORIAL ARMY

Majs (Prov) C H Carlton and H H Woollard are confirmed in their rank

Capt H Shield to be Maj

ROYAL AIR FORCE

M. D Rawkins and H Penman are granted short service commns as flying officers

INDIAN MEDICAL SERVICE

Lt -Cols A. Spitteler and J Norman Walker to be Bt.-Cols

Lt T A Doran to be Capt

The following temporary commissions have been granted : Amarnath Bajaj, Rangi Lal, and Kazi Tasadduq Hosain Khan to be Temp Lts

The King has approved the relinquishment of their temporary commissions by Lts Ragade Sanjiva Rao and Ponathil Balakrishna Kurup

PRINCESS VICTORIA AT IVER COTTAGE HOSPITAL.—Princess Victoria, who now resides at Iver, last week opened the enlarged and improved Iver, Denham, and Langley Cottage Hospital, which serves a comparatively extensive rural district on the south Buckinghamshire border near Uxbridge

"Audi alteram partem "

TREATMENT OF TUBERCULOSIS BY MR SPAHLINGER'S METHODS

To the Editor of The Lancet

Sir,—I am exceedingly grateful to Dr Leonard Williams for his letter in your last issue, calling my attention to the case of E A, who, he says, should have been included among the test cases given by Dr Arthur Latham to Mr Spahlinger in 1913–14 I may say at once that the case was not included because (1) he had no tuberculosis of the lung, and (2) he never received any injections of Mr Spahlinger's preparation in St George's Hospital

As Dr Williams, on no justifiable grounds, criticises unkindly the notes of the hospital, I ask your special permission, Sir, to publish this case in full, word for word, with the queries and underlinings just as it appears in the Medical Register of the Hospital

Medical Register of St George's Hospital, No 412–1914

Edward Allen Age 31 Occupation—porter

Under the care of Dr Latham Ward—William King

Bed No 16 Admitted 23rd March Discharged *6th April*

Diagnosis —? T B Lung No evidence

Patient complains of losing weight.

H P I *A fortnight before* Xmas patient had influenza He remained at home for eleven days and then returned to work After returning for four or five days he had a relapse of the influenza This resolved itself into acute rheumatism Patient was confined to bed for six or eight weeks He again returned to work and after a week had another attack of rheumatism Dr Spahlinger gave him an injection which apparently made him worse for a few days He then went to the French Hospital and gradually became better Patient had a second injection last Saturday

Patient has no cough and he does not spit up Occasionally spits up a little black phlegm night and morning in Winter months Does not sweat at night Never brought up blood Up to a fortnight ago patient was losing weight But since then is putting on weight Feels as if he is getting stronger Appetite *good* No headaches

P M H —Double pneumonia twelve years ago No history of Σ

F H —Nil *abnormal detected*

Habits —Non-drinker Smoker

C O A —Patient is a fairly well nourished man about 11 *stone in weight* Some pallor of face

Tongue —Clean and moist

Teeth —Satisfactory

Fauces—Healthy

Chest —Moves well and equally There appears to be some impairment of resonance *over* right apex behind On auscultation a few creps can be heard on deep inspiration It is doubtful whether these are tuberculous

Heart —No gross lesion discoverable

Abdomen —Nil abnormal detected

Knee jerks —Present

Eyes —React to light and accommodation.

Urine (see *notes on* chart)

23rd Mar Patient put to bed, Temperature 99 Pulse 108

26th Mar Patient does not expectorate or *cough at all* —so sputum not searched

27th Mar Opsonic reaction done q v

(Opsonic index to T B

1	*After night's rest*	0 85
2	After active exercise	0 77
3	After rest in bed	0 83

Mar 27/14 Signed E L Hunt)

Patient has been skied and (the usual) mottling suggestive of tuberculous (?) disease reported upon No crepitations now heard at apex behind 30th Mar. Patient feels quite well, gets up and about

1st April Dr Inman of the Brompton Hospital did his complement-fixation test, but he reports that the reaction was negative

4th April Injection of old tuberculin for diagnosis—no reaction

6th April Left Hospital without evidence of tubercle at all

I enclose a copy of the temperature chart The principal information from it is —

Urine Acid Sp Gr 1020 No albumin or sugar. Deposit of normal phosphates

Weight —23 Mar 11 st 4¾ lbs
30 Mar 11 st 6 lbs
6 Apr 11 st 9 lbs

After the evening of admission temperature was 98 6° F. on two occasions, otherwise *normal or below* Pulse extremes 56 and 96, usually 76 Respirations average 22

Treatment sheet shows —Diet—ordinary Haust Sennæ Co Oz ij o n, Ol Morrh C Malt drms ij t d s, Haust Ferri Arsenicalis oz j t d s p c

You will see, Sir, that Dr Latham used every then known examination (in the absence of sputum) *to see* if this man had any sign whatever of tuberculosis, this naturally being the first step in selecting a patient *on which to test a cure for that disease* The results are overwhelmingly negative Perhaps I should point out that radiography of the chest was at this time in its infancy, and the extent of normal mottling in the chest was not realised, so that no great importance was attached by cautious clinicians like Dr Latham to anything but gross lesions Unfortunately, the plates are destroyed after a certain time, so that I am not able to inspect the original

According to the man's story, as taken down by Dr Latham's clinical clerk on March 23rd, 1914, he had had *two* injections of Mr Spahlinger's preparations before entering St George's Hospital He certainly had *none in St George's* *Dr Williams has* pointed out to you in his letter how " irrelevant to the issue " is a case that had had three injections No doubt the patient's memory of the events in January to March, 1914, was better on March 23rd, 1914, than it is now Indeed, the tricks that memory may play us is well exemplified in his recollection of having weighed 8 st 1 lb, whereas he actually weighed 11 st 4¾ lb at the beginning of his fortnight in St George's And again his memory of Mr Spahlinger's treatment " for several weeks, receiving an injection on the average of one every two days " is sadly awry

I am hoping that Dr Williams will be kind enough to publish the original notes of the French Hospital' on which he was able to make a certain diagnosis of tuberculosis *before proceeding to treat the disease*

I have the permission of the Medical Registrar of St George's to show these notes, and those of the *Spahlinger series, to Dr* Williams if he could find time to meet me at the hospital If he knows of any other such cases that I have not included—and I may well have missed one or two in searching among some 2000 odd for 10 or 12—I will willingly look them up and publish them

It may be hoped for the sake of "one of Mr Spahlinger's most striking successes" that some convincing proof is forthcoming that this man ever suffered with pulmonary tuberculosis

I am, Sir, yours faithfully,
Thomas Nelson

Brook street, Grosvenor-square, W, Jan 10th, 1927

THE EDUCATION OF THE SURGEON.

To the Editor of The Lancet

Sir,—In my presidential address to the Section of Ophthalmology of the Royal Society of *Medicine* I referred to the important point that progress in ophthalmology was, in the future, to be looked for on the medical side, and later on in speaking of the education of the oculist I referred again to this matter. A few *days* later Sir Berkeley Moynihan in his admirable address to the Medical Society made the same statement in reference to *general* surgery, which he suggested *as an art* had almost reached its finality.

In The Lancet of Dec 4th 1926, " Incipiens and in that of Jan 1st, 1927, " Respiciens," referring to my address missed the point by writing under the heading of " Medicine *or* Surgery for the Oculist, while I said Medicine *and* Surgery—and of course

Sir Berkeley Moynihan said the same, in fact he suggested that the successful surgeon of the future would have to be not only a master of the art and craft of surgery, but also be a pathologist, bacteriologist, chemist, and physician So that it is possible in the future that candidates for hospital surgical appointments would be required to have the diploma of F R C S and the degree of M D

This ought to suit " Incipiens " as he says he does not propose to lower the standards He says he wants to see these two diplomas equalised What does he mean by this? The F R C S, England is considered the highest surgical diploma, and the M D the highest medical diploma, and unlike the F R C P they are within the reach of all Is this the equalisation he refers to? Because only in this sense could they be equal.

I cannot agree with anything that " Respiciens " writes, but one remark is calculated to give so wrong an impression that I must refer to it He says, " The tragedy is that men are encouraged to take up ophthalmology in order to obtain their services as clinical assistants and house surgeons, and then, no matter what their attainments, their further progress is debarred, not by an examination in ophthalmology, but by a purely surgical examination " The very large majority of men who take appointments in the eye wards of a general hospital or in an ophthalmic hospital do so because they know how extremely valuable the knowledge gained will be in general practice, and only a small proportion aim at specialising in eye work Where is the tragedy?

One thing is certain, whatever extra knowledge the general or special surgeon may acquire, he must first and foremost be a surgeon, have the tactus eruditus, and be supple and clever with his fingers and hands, and the very derivation of the word and the obsolete name for it—viz, " chirurgeon," implies this I am, Sir, yours faithfully,

Jan 10th, 1927 ERNEST CLARKE

PELLAGRA IN NYASALAND

To the Editor of THE LANCET

SIR,—In your issue of Jan 8th Dr H M Shelley contributes some observations which I may be allowed perhaps to criticise The discovery of a number of cases of pellagra in Nyasaland by myself in 1910 constituted the first record of the disease in Africa south of Lower Egypt, Algiers, and the Red Sea coast with the exception of a few cases seen and diagnosed by Sandwith on Robben Island, none having been described elsewhere in South Africa

My early cases formed the subject of a preliminary communication to the Royal Society of Tropical Medicine and Hygiene [1] The following year a fuller report was published,[2] which has apparently escaped Dr Shelley's notice In that paper I showed that the maize theory was untenable, and I went some way to incriminating the absence of some food factor as playing a part in the ætiology of the disease, while showing that the pathological changes were due to a toxæmia I had already shown that, although the disease was rife in the Central Gaol, cases occurred elsewhere among the general population From the date of my second communication up to the commencement of the late war I had collected a considerable amount of further information which was never published, but tissues from the bodies of nine pellagrins who were submitted to complete post-mortem examination were sent to this country and formed the subject of a preliminary paper by S A Kinnier Wilson,[3] chiefly on the neurological side The pathological changes described by this authority cannot here be discussed at length, suffice it to say that they are those of a chronic diffuse pseudo-systematised degeneration, affecting all portions of the peripheral and central nervous system, and resembling somewhat the condition found in subacute combined degeneration of the cord with no evidence of a vascular or meningeal reaction to infection The changes in the nervous system are toxic in origin, Wilson, from the pathological side, says " It is probable that an ascending toxic lymph stream invades the cord via the lumbar and dorsal posterior roots and that the effects of the toxæmia appear either simultaneously in the nerves and cord or previously in the former," corroborating the following statement made in my first communication from clinical evidence " Taking into consideration the diffuse nature of the cord lesions and the absence of systematisation it would seem probable that the nervous lesions are produced by a toxin entering the theca by the lymphatic spaces of the posterior roots "

The toxic process was, therefore, long ago proved, but Dr Shelley was apparently unaware of Wilson's findings Dr Shelley speaks of a " neuritis of certain peripheral nerves " and of " subacute and combined sclerosis of the cord," whereas the process is a degenerative one He further suggests that " the neuritis produces trophic changes in the areas of skin supplied by these nerves," adding that " these trophic lesions of the skin appear most marked on those parts of the body which are exposed to sunlight, but some cases have been seen with well-marked skin signs on the scrotum and buttocks " He thus appears to believe that the exanthem is the result of a neuritis which affects particular nerves Observations made on a large number of cases have, however, proved to me that the sun's radiations are the only factor in causing the typical distribution of the rash and that the areas involved do not strictly correspond to root areas, much less to any peripheral nerves (In his diagram Dr Shelley shows roots areas under the designation of cutaneous nerves distribution) The sensitisation of the skin to the sun's rays may more probably be due to a circulating toxin like hæmatoporphyrin or phyto-porphyrin

The affection of the scrotal skin, which was, I think, first pointed out by myself, may result from heat and moisture Dr Shelley does not seem to have noticed another condition which I first described in 1911—namely, a rhagades-like soreness of the muco-cutaneous junction at the angles of the mouth, the external canthus of the eye, and at the free margin of the prepuce—a very valuable early sign in many cases

Dr Shelley attempts to find a parallel between the signs in pellagra and myxœdema which, I think, should not be allowed to go unchallenged Of both he says " skin thickened and rough " In pellagra the skin, except where it is the site of the rash or in patients who have not washed or attended to their skin, is not thickened and rough Of both he says " slight œdema present " In pellagra, except in late cases, œdema is not found, while in myxœdema there is no true œdema but a characteristic distribution of subcutaneous infiltration never seen in pellagra Of both he says " skin dry and scaly "—this is only true of the uncared-for skin in a native pellagrin " Tongue swollen "—the condition of the tongue in the two diseases is about as different as possible, the characteristic tongue of pellagra is never seen in myxœdema " Mental dullness and apathy " is ascribed to both conditions—the native pellagrin may appear dull but the mental characteristics in the two conditions in no way resemble each other While it is well known that the thyroid suffers, in common with nearly every other organ of the body, in pellagra and that true myxœdema and pellagra may coexist, there is little evidence that the picture in pellagra is in any particular way due to hypothyroidism On the other hand, while the beneficial effects produced by the administration of thyroid is of interest, the exact mode of its action would require, however, considerable investigation, thyroid is useful in a large variety of conditions

For the reasons given above I am of opinion that the three main conclusions which Dr Shelley draws from his observations are not essentially correct—namely, 'that there is in pellagra · (1) A deficiency in thyroid secretion (2) A neuritis of certain nerves in preference to others (3) Skin lesions corresponding to the cutaneous distribution of those nerves" And I should like to protest against the view often quoted by those who hold that pellagra is a deficiency disease—namely, that the absence of some element produces pathological changes. The absence of something cannot produce anything! In pellagra, as in beri-beri, it is believed that in the absence of some vital element a toxin may develop and produce the pathological changes in the body.

INFLUENZA AND SOME GLOOMY REFLECTIONS

To the Editor of THE LANCET

SIR,—In common with the majority of my professional brethren I am at the present time called upon to visit large numbers of people suffering from some disease to which the label of ' influenza is perforce given This annual experience is always attended by considerable personal fatigue and discomfort and, in my case at any rate, by a certain amount of shame The laity jibe at our profession because we cannot cure a cold, we acquire protective catchwords with which to change the conversation; we suppress our irritation and recover our self-esteem as best we can —the charge remains true. When the common cold is epidemic and approaches a severity sufficient to cause it to be renamed 'influenza," the layman s accusation becomes a serious one, and that is why I am ashamed both of myself and my profession at this moment Nine years ago some 20 million human beings died within 12 months, apparently of this same disease, and as a member of that group of their fellows which is supposed to be interested in the technique of the suppression of such catastrophes I find something frankly disgraceful in the complacent indifference of the bacteriologists physicians and public health authorities at a time when serious endeavour could be made towards discovering the nature and cure of this disease

Particularly are the bacteriologists to blame Any of us who have attended their meetings and discussions have heard technicians, not all equally competent, recount their experience in growing a microbe which they call the influenza bacillus the discussion being enlivened by adherents of hypotheses which leave death and disease unaffected They appear to be making no serious effort to discover the causal organism. What is being done about the work of Olitzky and Gates? Whether this work is correct or not it is sufficiently suggestive to merit large-scale investigation, it has gone on for a number of years neither dogs nor monkeys are required for its repetition and there is no rival set of observations with any serious number of adherents But I have not met a single bacteriologist in this country who is actively studying this work.

There are certain researches which stand out as being of such immense potential importance that any self-respecting nation should immediately take full and proper steps to refute or confirm them The work of Rosenthal on fæcal sepsis is one instance the work of Banting and Best on insulin is another the work of Gye on cancer is a third and the work of Olitzky and Gates is clearly a fourth Yet as far as I know there is no representative body of bacteriologists in this country who can with authority tell us whether Olitzky and Gates have isolated the virus of influenza or not And until they do we remain futile in the eyes of the layman

Physicians and public health authorities I blame to a lesser degree for this supineness But physicians might at least spare us imbecile articles in the newspapers on the prevention and cure of influenza which may endanger the mental balance of the convalescent Of what use is it to tell working girls not to eat white bread or to warn clerks to take more exercise in order to escape influenza when we have no gleam of certitude as to the invading agent in that disease? Can these authorities not join the natives of the Solomon Islands or the peasants of Siberia and gorge themselves with vitamins in silence until the next pandemic carries them off? As to the public health authorities their responsibility is great. They have the power to enforce investigation by the laboratories Instead of doing so they continue to exhibit tact in their dealings with their professional brethren, and diplomacy and inertia make happy bedfellows

Breaking away from these gloomy reflections (which are shared by many) I must return to my work, which will probably be less interrupted if I subscribe myself,

Yours faithfully,

Jan 8th, 1927 X.

ADOLESCENT ALBUMINURIA

To the Editor of THE LANCET

SIR,—It must be confessed that the want of a simple and reliable test for the condition of the kidneys is an opprobrium to modern medicine. The injection of dyes and blood examination are disappointing where most required; indeed. there seems no reason of an *a priori* nature why these methods should detect slight renal defects If we are thrown back on urinalysis two desiderata are important in my experience The first is some common agreement as to what constitutes albuminuria If one practitioner examines by heating and acidulating the upper layers of urine in the test-tube. or by salicyl-sulphonic acid while another relies on nitric acid or on heating the bottom of the test-tube, the discrepancy in results will be important. The second desideratum is the following up of the clue afforded by the modifying action of rest One often asks oneself: What is the active element in " rest " Is it the horizontal position, equable warmth, muscular immobility cessation of the ingestion of proteids or raising of a serum threshold? This is a fascinating problem which should make appeal to many a biochemist and which might eventually throw light on the early stages of nephritis

I am, Sir, yours faithfully,

Belfast, Jan 4th, 1927. R M. FRASER, M.D.

BACTERIAL CONTENT OF ICE-CREAM

To the Editor of THE LANCET.

SIR—The report by Dr. E. G. Rawlinson that appears under this heading in THE LANCET of Dec 18th should be of great interest to those who study health as a positive entity and not merely as the absence of disease The evidence, I believe so far unchallenged, shows that great quantities of coliform organisms, streptococci, and *B enteritidis sporogenes* were consumed in ice-cream last summer, and nobody one pennyworth the worse—i e no resulting epidemic reported One wonders whether an infantile type of reaction such as ' D and V" would not have been a healthier response on the part of the consumer, especially if as Dr Rawlinson suggests these organisms may act detrimentally later on

The strains in these specimens must have come from a variety of sources, but one naturally wonders whether the one common factor the low temperature played a part in temporarily inactivating the cultures. Whatever the temperature of the ice-cream received at the laboratory it is unlikely that the public would buy and eat it unless cold enough to appear semi-solid. If this is the explanation the ice-cream vendor s role is that of a public alimentary vaccinator!

The increase in numbers of street vendors and the more rapid methods used in distribution in recent years render Dr Rawlinson s results still more significant —I am, Sir, yours faithfully

J. L CHEESMAN.

Public Health Department, Leyton, E, Jan 10th, 1927

Medical News.

UNIVERSITY OF CAMBRIDGE —At a recent examination the following candidates were approved —

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

Part I —Philippe Bauwens, Ernest Edwin Carter, Gerald Chambers James Cran Coutts Andrew Murray Craib, Robert McGregor Cleland Crawford, Jane Grace Evans-Freke Cummins, Harry Fisher Nathaniel Fram, Denys Bouhier Herbert Hallett, Minnie Edith Hope William Hougham Hudson, John Joseph Luddy, Alfred Tadros Makar, Walter Morrish Abraham Orliansky, Raghuber Dayal Saigol William Hugh Steele, Edgar James Tyrrell Samuel Anthony Withers, and Kenneth John Yeo

UNIVERSITY OF LONDON —At recent examinations the following candidates were successful —

M D

Branch I, Medicine —Elizabeth Mary Cowie Edward Revill Cullinan, Francis Davies, Vivian Feldman, Dorothy Gibson, Reginald Sleigh Johnson Ardeshir Jehangirshah Kohiyar, William Austin Robb, Norman William Snell, and John Greenwood Wilson

Branch III Psychological Medicine —Emma Marjorie Store

Branch IV, Midwifery and Diseases of Women —Harold Jordon Malkin, Henry Kenneth Victor Soltau, and Edith Emily Stephens

Branch V, State Medicine —Donald Davidson

M S

Branch I, Surgery —George Frederick Gibberd, and Walter Roworth Spurrell

UNIVERSITY OF LIVERPOOL —At recent examinations the following candidates were successful —

DIPLOMA IN PUBLIC HEALTH

New Regulations —J S Bradshaw, Helen Standring, S A Talib, O F Thomas, and T S Townsend

Old Regulations —Olive Llewellyn Jones, Eleanor Lancelot, and Vera M Macfarlane

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS —The annual general meeting will be held at 122, Harley-street, London, W, on Jan 17th, at 3 P M, when a discussion on the Observation Case will be opened by Dr. F R G Heaf and Dr N Bardswell It is hoped that there will be several five-minute papers from other members

CHELSEA CLINICAL SOCIETY —A meeting of this society will be held in the Governor's Committee Room at St George's Hospital on Tuesday, Jan 18th, at 8 30 P M., when Dr J D Rolleston will open a discussion on the Practical Results of Recent Researches in Infectious Disease Dr R A O'Brien and other speakers will also take part

SUGGESTED AMALGAMATION OF EYE HOSPITALS —Dr E Graham Little, M P, suggests that the Royal Westminster Ophthalmic, the Central London Ophthalmic, and the Western Ophthalmic Hospitals, which, among them, have 98 beds, should be amalgamated They are all preparing to extend or rebuild, and Dr Little urges the economies that would result from replacing three small hospitals by one "effective central institution" with between 100 and 150 beds He points out that opposite the site of the Central Ophthalmic Hospital in Judd-street, W C, there is an area of land ready for immediate occupation that could at present be secured "which would afford generous accommodation for a hospital of 150 beds or more"

A HOSPITAL FOR OFFICERS' WIVES —The Queen Mary wing of the Louise Margaret Hospital at Aldershot has now been opened Accommodation is provided in the first place for the wives of officers of the Aldershot Command, but, when empty beds permit, the wives of officers serving in other commands, including India, or of officers on half-pay, can benefit There are three beds for general cases and two for maternity cases, with two beds and six cots for children The inclusive fees are 15*s* per day

WASTE TIN FOR HOSPITALS —Commander Moore, the Appeal Secretary of King's College Hospital, is organising a scheme for the collection of empty tin tubes which have contained tooth-paste and medical compounds These tubes are stated to contain 96 per cent of pure tin, and it is proposed to sell the metal for the benefit of the hospital Since the price of tin exceeds £300 a ton and the supply is limited, Commander Moore hopes to derive a large sum from the collection of receptacles that are at present thrown away

BELFAST HOSPITAL FOR SICK CHILDREN —This hospital of 45 beds, has become so unsuitable and inadequate that it is to be rebuilt at a cost of £80 000 The Belfast Corporation have presented a site on the Grosvenor-road

SOUTH-WEST LONDON CHEMISTS' ASSOCIATION —A meeting of this Association will be held at Stevens's Bijou Hall, Bromell's-road, Clapham, on Tuesday, Jan 18th, at 8 30 P M, when Mr L. Carnac Rivett will lecture on Some Aspects of Modern Surgery

NEW NURSES' HOME AT KINGSTON —The Kingston-on-Thames Board of Guardians is about to erect a new home for the nurses at the Kingston and District Hospital which has 800 beds, and the first sod was cut last week by Mr H Broome, the chairman of the board The home will cost £100,000

THE LATE SIR H E DIXEY —The death occurred suddenly on Jan 6th at his home in Great Malvern of Sir Henry Edward Dixey at the age of 75 He was educated at the University of Aberdeen, where he graduated M B C.M, in 1878 and M D in 1881, and after qualifying he was for a time house surgeon in Preston Royal Infirmary He retired from practice some years ago, and was knighted in 1925 in recognition of political and public services He took an active interest in social, civic, and political matters, was an alderman of the Worcestershire County Council, and a former sheriff He interested himself greatly in public health, was a keen advocate of open air schools, took an active part in the campaign against tuberculosis, and did excellent work in connexion with the Knightwick Sanatorium.

PENSIONS MINISTRY HOSPITALS —The ninth annual report of the Ministry of Pensions, which comes down to March 31st, 1926, shows that there are still 22 hospitals and 79 clinics under the direct control of the Ministry In addition the Ministry reserves accommodation in many civil institutions of a similar nature "to provide the most approved and modern forms of treatment for injuries and diseases of types, peculiarly related to war service, for which adequate provision is not otherwise obtainable" There has been a substantial decrease in the cost of medical boards owing to the smaller number of conditional pensioners requiring examination

SOCIETY OF MEDICAL OFFICERS OF HEALTH —A meeting of this Society will be held at 1, Upper Montague-street, Russell-square, London, W C, on Friday, Jan 21st, at 5 P M, there will be a discussion on the Education of the Public in regard to Modern Methods of Disease Prevention (Premunisation, Immunisation, &c) from the point of view of the Government Department (Dr S Monckton Copeman, F R S), the Medical Officer of Health (Dr C W Hutt), the Press (Lord Riddell), the Public (Dean Inge) and the Laboratory Director (Prof J C G Ledingham, F R S)

BRITISH EMPIRE CANCER CAMPAIGN —In the absence of Lord Cave, Sir Charles Gordon-Watson presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on Jan 11th Sir D'Arcy Power was elected a member of the Council on the nomination of the Imperial Cancer Research Fund The grant of £600 for the whole-time services of a medical officer to the London Association of the Medical Women's Federation, which is using a quantity of the Campaign's radium, was renewed for a further period of one year A grant of £500 was made to Mr F C Pybus, F R C S, for expenses to be incurred by the employment of an assistant in connexion with research at Newcastle-on-Tyne Reports were received from the representatives of the Campaign who visited American and continental cancer research laboratories It was stated that the journal of abstracts, known as the *Cancer Review*, published by the British Empire Cancer Campaign, has been much appreciated in the United States, serving as a connecting link between research workers in America and in this country A confidential report was received from the deputation of the Campaign which visited Liverpool to investigate the Blair Bell lead treatment, and an application was considered from St Bartholomew's Hospital, London, for assistance in further investigation of the treatment with lead A grant, not exceeding £1000, and to be reconsidered from year to year for the next five years, was made to this hospital for carrying out new investigations beyond the facts already established by Prof Blair Bell and the workers in Liverpool The investigations will be under the control of a scientific committee consisting of Sir Thomas Horder, Sir Charles Gordon-Watson, Mr. W D Harmer, Mr J E H Roberts, Mr M Donaldson, Dr G Graham, Prof F L Hopwood, Mr J B Hume, and Dr R G Canti The Council expressed the hope that the Liverpool Medical Research Organisation will link up with the impending appeal of the British Empire Cancer Campaign of Lancashire and Cheshire, which has already been joined by Manchester University Sir William Willcox was elected a member of the Preliminary Inquiry Committee of the Campaign

DONATIONS AND BEQUESTS.—Mr. W. R. Morris, the motor-car manufacturer, has given £101,000 to St. Thomas's Hospital.—Mr. John Dallas, of Glasgow, has given £1500 to the Royal Infirmary, Glasgow, for the endowment of a bed.

THE LATE DR. HAROLD HEBBLETHWAITE.—The death has occurred at Burley-in-Wharfedale, Leeds, of Harold Hebblethwaite, one of the best-known practitioners in Wharfedale. He was born at Bradford in 1862, received his medical education in what was then the Yorkshire College, Leeds, and the Leeds Medical School, and qualified as M.R.C.S. Eng. and L.S.A. Lond. in 1887, having been prosector in the anatomical department of the College. He was for many years associated with the Volunteers and afterwards with the Territorials, and during the late war acted as medical officer of the Brockton camp for prisoners-of-war. He was medical officer of health for Burley-in-Wharfedale. He took much interest in St. John Ambulance Association in Staffordshire and was one of the examiners for this body. Dr. Hebblethwaite leaves a daughter and two sons, the younger of whom, Dr. A. S. Hebblethwaite, is resident medical officer of the Leeds City Hospital for Infectious Diseases.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Jan. 17th.—8.30 P.M., SOCIAL EVENING. Fellows, Members of Sections, and their friends will be received in the Library by the President and Lady Berry. At 9.30 P.M. Prof. A. W. Sheen will give an address on Medicine in Ancient Greece (with illustrations).

TUESDAY.—5.30 P.M., SPECIAL GENERAL MEETING OF FELLOWS. To consider and if approved to confirm the alterations in the by-laws made by the Council of the Society so as to provide for the office of honorary editors. Ballot for election to the Fellowship. 8.30 P.M., PATHOLOGY. G. M. Findlay: Tar Tumours in Rats. J. A. Arkwright: The Values of Different Kinds of Antigens in T.A.B. Vaccines. P. Fildes: Tetanus. S. P. Bedson: Some Observations on the Filtration of Herpes Virus Through Collodion Membranes.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Dr. A. Currie: The Medical History of the First Three Wives of Henry VIII. and Their Offspring. Mr. W. R. Dawson: Contributions to the History of Mummification. 8.30 P.M., SURGERY. Paper: Dr. J. M. T. Finney (of the Johns Hopkins Hospital, Baltimore, U.S.A.): Some Considerations Concerning the Pathology and Treatment of Gastric and Duodenal Ulcers.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Mr. H. S. Souttar: Demonstration of Steam Cautery and Cases Treated thereby. Dr. H. Semon: Cases Treated by Steam Cautery. Other cases will be shown.

FRIDAY.—The Library will be open until 10 P.M. 4.30 P.M., BALNEOLOGY AND CLIMATOLOGY. (Council meeting at 4 P.M.) Dr. Llewellyn J. Llewellyn will open a discussion on Climacteric Arthritis. Speakers: Dr. Barnes Burt, Dr. Warren Crowe, Dr. F. G. Thomson, Dr. R. G. Gordon, Dr. Bassett Jones, Dr. W. J. Midelton, Dr. Halls Dally, Dr. Vincent Coates, Dr. S. W. Patterson, and Dr. M. B. Ray. 8 P.M., OBSTETRICS AND GYNÆCOLOGY. Joint meeting of the Section with the Medico-Legal Society. The Right Honble. Lord Justice Atkin will preside. Discussion on the Ethical, Legal, and Medical Aspects of Abortion. Speakers: Dr. J. S. Fairbairn, Lord Riddell, Dr. T. Watts Eden, and Sir Travers Humphreys. 8.30 P.M., ELECTRO-THERAPEUTICS. Discussion on *Light Treatment in Surgical Tuberculosis.* Opener: Sir Henry Gauvain.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Jan. 20th.—8.15 P.M., Demonstration at 7.45 P.M. A paper on the Hæmoglobinurias will be read by Prof. J. W. W. Stephens, F.R.S., of the Liverpool School of Tropical Medicine.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Jan. 17th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 2 P.M., Mr. Donald Armour: Operations. 4 P.M., Mr. Tyrrell Gray: Abdominal Pain.

TUESDAY.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Owen: Medical Out-patients. 4 P.M., Dr. Price: Methods of Anæsthesia in Special Cases.

THURSDAY.—12 noon, Mr. Simmonds: Demonstration of Fractures. 3 P.M., Sir Henry Simson: Demonstration of Fractures. 3 P.M., Sir Henry Simson: Gynæcological Wards. 4 P.M., Dr. Snowden: The Development of the Mind.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin Dept. 11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Mitsto: Throat, Nose and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Mr. Banks Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 5 P.M., Operations, Medical, Surgical and Special Out-patient Departments. Saturdays, 10 A.M. to 1 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Jan. 17th, to SATURDAY, Jan. 22nd.—COMBINED COURSE IN DISEASES OF CHILDREN at the Children's Clinic and the Royal Free Hospital. Afternoons and some mornings.—PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. Daily, 10.30 P.M. to 5.30 P.M., intensive course as per syllabus. Second week.—ROYAL EAR HOSPITAL, Southwark. Mon., Mr. Latchworth; Tues., Mr. Griffiths; Thurs., Mr. MacCall; Fri., Mr. Dorrell. Special demonstrations at 3 P.M. free to members of the medical profession.—ST. MARY'S HOSPITAL, Paddington, W. Wed., 2 P.M., Mr. Fitzwilliams: Ward Round. Free to members of the medical profession.—BETHLEM ROYAL HOSPITAL, S.E. Tues. and Sat., 11 A.M., Lecture demonstrations on Psychoses. All information as to fees, &c., obtainable from the Secretary of the Fellowship of Medicine, 1, Wimpole-street, W. 1.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, The Prince of Wales's General Hospital, N.

INTENSIVE COURSE.

MONDAY, Jan. 17th.—Dr. D. Kirkhope: The Prophylaxis of Diphtheria and Scarlet Fever.

TUESDAY.—Dr. I. R. Yealland: The Treatment of Anxiety Neurosis.

WEDNESDAY.—Mr. Aubrey Goodwin: The Modern Treatment of Toxæmias of Pregnancy.

THURSDAY.—Dr. A. J. Whiting: Spectral Heart Disease.

FRIDAY.—Dr. J. Browning Alexander: Ætiology and Treatment of Rheumatoid Arthritis.

Morning demonstrations, 10.30 to 1 P.M. Hospital clinics, 2 to 4 P.M. Clinical lectures, 4.30 P.M.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Jan. 21st.—4 P.M., Dr. Andrew Wylie: Dysphagia.

ROYAL NORTHERN HOSPITAL POST-GRADUATE COURSE.

TUESDAY, Jan. 18th.—3.15 P.M., Mr. T. T. Higgins: The Treatment of Varicose Veins by Injection. Free. Tea at 4.15 P.M.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-sq., W.C.

TUESDAY, Jan. 18th.—9 P.M., Mr. J. M. T. Finney: Surgery of the Stomach and Duodenum.

WEDNESDAY.—9 P.M., Mr. F. Moore: Acute Glaucoma.

THURSDAY.—Prof. A. W. Sheen: Early Recognition of Surgical Emergencies. Dinner, 8 P.M.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Jan. 20th.—4 P.M., Mr. Lloyd: Retropharyngeal Abscess.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

THURSDAY, Jan. 20th.—5 P.M., Dr. Kenneth Bailey: Pathology Demonstration.

Appointments.

Westminster Hospital: DELITTLE, D. L., M.B., B.S., OSTER, M. N., L.R.C.P. Lond., M.R.C.S., House Physicians; LAVERS, A. H., L.R.C.P., M.R.C.S., CORBETT, C., L.R.C.P. Lond., M.R.C.S., House Surgeons; MCKELVEY, M. P., L.R.C.P. Lond., M.R.C.S., Resident Obstetric Assistant.

Certifying Surgeon under the Factory and Workshop Acts: PUGH, A. B., L.R.C.P. Lond., M.R.C.S. (Torrington); ASHCROFT, P. A., L.R.C.P. Lond., M.R.C.S. (Littleborough).

Vacancies.

For further information refer to the advertisement columns.

Adelaide University, South Australia.—Elder Professorship of Anatomy. £1100.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.

Birmingham General Hospital.—Med. Reg. and Res. M.O. £155.

Bradford Royal Infirmary.—H.S. £150.

Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsthetist. At rate of £130. Also Hon. Asst. P. for Electrical and X Ray Dept.

City of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

Medical News.

UNIVERSITY OF CAMBRIDGE —At a recent examination the following candidates were approved —

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

Part I —Philippe Bauwens, Ernest Edwin Carter, Gerald Chambers James Cran Coutts, Andrew Murray Craib, Robert McGregor Cleland Crawford, Jane Grace Evans Freke Cummins, Harry Fisher, Nathaniel Fram, Denys Bouhier Herbert Hallett, Minnie Edith Hope, William Hougham Hudson, John Joseph Luddy, Alfred Tadros Makar, Walter Morrish Abraham Orliansky, Raghuber Dayal Saigol, William Hugh Steele, Edgar James Tyrrell Samuel Anthony Withers, and Kenneth John Yeo

UNIVERSITY OF LONDON —At recent examinations the following candidates were successful —

M D

Branch I, Medicine —Elizabeth Mary Cowie Edward Revill Cullinan Francis Davies, Vivian Feldman, Dorothy Gibson, Reginald Sleigh Johnson, Ardeshir Jehangirshah Kohiyar, William Austin Robb, Norman William Snell, and John Greenwood Wilson

Branch III, Psychological Medicine —Emma Marjorie Store

Branch IV, Midwifery and Diseases of Women —Harold Jordon Malkin, Henry Kenneth Victor Soltau, and Edith Emily Stephens

Branch V, State Medicine —Donald Davidson

M S

Branch I, Surgery —George Frederick Gibberd, and Walter Roworth Spurrell

UNIVERSITY OF LIVERPOOL —At recent examinations the following candidates were successful —

DIPLOMA IN PUBLIC HEALTH

New Regulations —J S Bradshaw, Helen Standring, S A Talib, O F Thomas, and T S Townsend

Old Regulations —Olive Llewellyn Jones, Eleanor Lancelot, and Vera M Macfarlane

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS —The annual general meeting will be held at 122, Harley-street, London, W., on Jan 17th, at 3 P M, when a discussion on the Observation Case will be opened by Dr F R G Heaf and Dr N Bardswell It is hoped that there will be several five-minute papers from other members

CHELSEA CLINICAL SOCIETY —A meeting of this society will be held in the Governor's Committee Room at St George's Hospital on Tuesday, Jan 18th, at 8 30 P M, when Dr J D Rolleston will open a discussion on the Practical Results of Recent Researches in Infectious Disease Dr R A O'Brien and other speakers will also take part

SUGGESTED AMALGAMATION OF EYE HOSPITALS —Dr E Graham Little, M P, suggests that the Royal Westminster Ophthalmic, the Central London Ophthalmic, and the Western Ophthalmic Hospitals, which, among them, have 98 beds, should be amalgamated They are all preparing to extend or rebuild, and Dr Little urges the economies that would result from replacing three small hospitals by one "effective central institution" with between 100 and 150 beds He points out that opposite the site of the Central Ophthalmic Hospital in Judd-street, W C, there is an area of land ready for immediate occupation that could at present be secured "which would afford generous accommodation for a hospital of 150 beds or more"

A HOSPITAL FOR OFFICERS' WIVES —The Queen Mary wing of the Louise Margaret Hospital at Aldershot has now been opened Accommodation is provided in the first place for the wives of officers of the Aldershot Command, but, when empty beds permit, the wives of officers serving in other commands, including India, or of officers on half-pay, can benefit There are three beds for general cases and two for maternity cases, with two beds and six cots for children The inclusive fees are 15*s* per day

WASTE TIN FOR HOSPITALS —Commander Moore, the Appeal Secretary of King's College Hospital, is organising a scheme for the collection of empty tin tubes which have contained tooth-paste and medical compounds These tubes are stated to contain 96 per cent of pure tin, and it is proposed to sell the metal for the benefit of the hospital Since the price of tin exceeds £300 a ton and the supply is limited, Commander Moore hopes to derive a large sum from the collection of receptacles that are at present thrown away

BELFAST HOSPITAL FOR SICK CHILDREN —This hospital, of 45 beds, has become so unsuitable and inadequate that it is to be rebuilt at a cost of £80,000 The Belfast Corporation have presented a site on the Grosvenor-road

SOUTH-WEST LONDON CHEMISTS' ASSOCIATION —A meeting of this Association will be held at Stevens's Bijou Hall, Bromell's-road, Clapham, on Tuesday, Jan 18th, at 8 30 P M, when Mr L Carnac Rivett will lecture on Some Aspects of Modern Surgery

NEW NURSES' HOME AT KINGSTON —The Kingston on-Thames Board of Guardians is about to erect a new home for the nurses at the Kingston and District Hospital which has 600 beds, and the first sod was cut last week by Mr H Broome, the chairman of the board The home will cost £100,000

THE LATE SIR H E DIXEY —The death occurred suddenly on Jan 6th at his home in Great Malvern of Sir Henry Edward Dixey at the age of 75 He was educated at the University of Aberdeen, where he graduated M.B C M, in 1878 and M D in 1881, and after qualifying he was for a time house surgeon in Preston Royal Infirmary He retired from practice some years ago, and was knighted in 1925 in recognition of political and public services He took an active interest in social, civic, and political matters, was an alderman of the Worcestershire County Council, and a former sheriff He interested himself greatly in public health, was a keen advocate of open air schools, took an active part in the campaign against tuberculosis, and did excellent work in connexion with the Knightwick Sanatorium

PENSIONS MINISTRY HOSPITALS —The ninth annual report of the Ministry of Pensions, which comes down to March 31st, 1926, shows that there are still 22 hospitals and 79 clinics under the direct control of the Ministry In addition the Ministry reserves accommodation in many civil institutions of a similar nature "to provide the most approved and modern forms of treatment for injuries and diseases of types, peculiarly related to war service, for which adequate provision is not otherwise obtainable" There has been a substantial decrease in the cost of medical boards owing to the smaller number of conditional pensioners requiring examination

SOCIETY OF MEDICAL OFFICERS OF HEALTH —A meeting of this Society will be held at 1, Upper Montague-street, Russell-square, London, W C, on Friday, Jan 21st, at 5 P M, there will be a discussion on the Education of the Public in regard to Modern Methods of Disease Prevention (Premunisation, Immunisation, &c) from the point of view of the Government Department (Dr S Monckton Copeman, F R S), the Medical Officer of Health (Dr C W Hutt), the Press (Lord Riddell), the Public (Dean Inge), and the Laboratory Director (Prof J C G Ledingham, F R S)

BRITISH EMPIRE CANCER CAMPAIGN —In the absence of Lord Cave, Sir Charles Gordon-Watson presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on Jan 11th Sir D'Arcy Power was elected a member of the Council on the nomination of the Imperial Cancer Research Fund The grant of £600 for the whole-time services of a medical officer to the London Association of the Medical Women's Federation, which is using a quantity of the Campaign's radium, was renewed for a further period of one year A grant of £500 was made to Mr F C Pybus, F R C S, for expenses to be incurred by the employment of an assistant in connexion with research at Newcastle-on-Tyne Reports were received from the representatives of the Campaign who visited American and continental cancer research laboratories It was stated that the journal of abstracts, known as the *Cancer Review*, published by the British Empire Cancer Campaign, has been much appreciated in the United States, serving as a connecting link between research workers in America and in this country A confidential report was received from the deputation of the Campaign which visited Liverpool to investigate the Blair Bell lead treatment, and an application was considered from St Bartholomew's Hospital, London, for assistance in further investigation of the treatment with lead A grant, not exceeding £1000, and to be reconsidered from year to year for the next five years, was made to this hospital for carrying out new investigations beyond the facts already established by Prof Blair Bell and the workers in Liverpool The investigations will be under the control of a scientific committee consisting of Sir Thomas Horder, Sir Charles Gordon-Watson, Mr. W D Harmer, Mr J E H Roberts, Mr M Donaldson, Dr G Graham, Prof F L Hopwood, Mr J B Hume, and Dr R G Canti The Council expressed the hope that the Liverpool Medical Research Organisation will link up with the impending appeal of the British Empire Cancer Campaign of Lancashire and Cheshire, which has already been joined by Manchester University Sir William Willcox was elected a member of the Preliminary Inquiry Committee of the Campaign

COLONIAL HEALTH REPORTS

Bechuanaland

In the report on the affairs of this Protectorate in South Africa for 1925–26 it is stated, in the section devoted to medical matters, that during the year the health conditions in general had been better than for some years past Notwithstanding the intense heat of the summer the mass of the population did not appear to have been affected adversely Both in type and incidence the prevailing diseases were less severe and widespread, and the economic life of the country may be said to have suffered little or no disturbance from their effects This was due no doubt, to the abundance of food supplies available in the resources of stored grain and the good grazing following upon last year's heavy rainfall As in the past, malaria and syphilis came first in order of importance, but respiratory and gastro-intestinal troubles —as for the most part having a common origin in malarial infection—took a high place in the list Epidemic outbreaks were confined to influenza colds and whooping-cough Of other infections, sporadic cases of measles rubella and amaas (mild small-pox) were reported here and there A special feature as regards the chest complications associated with some of these was the tendency to run a favourable course During the months of May and June, however, an unusual mortality amongst natives, including bushmen, was reported from the Kalahari In all about 100 persons were said to have died; but, although it was impossible to verify the number to a certainty, there is no doubt that the death-rate was unusual The symptoms pointed to severe malaria complicated with pneumonia following upon the heavy rains of the preceding months The natives reported that mosquitoes in such numbers had never before appeared There are tracts in these regions where rain does not fall more frequently than once in a generation, and if the rainfall is then heavy the eggs deposited by insects during many years are brought to life Provision has been made for building a modern hospital at Serowe and a small hospital hut at Maun, N'gamiland The returns of diseases are the highest recorded in the history of the territory This is more the result of increased facilities afforded for observation and treatment, through the extension of the medical service, than of undue prevalence or severity At Gabarones and Molepolole the number of treatments and attendances for the year was 3880 Of these 53 were hospital cases (six Europeans, 47 natives), there were three deaths At Kanye the total number of individual cases treated—both indoor and outdoor—was 1426, of whom 43 were Europeans Sixty-two cases were treated in the Mission Hospital and 49 operations performed, the recorded deaths were three At Francistown 861 cases were attended and treated At Maun, N'gamiland, 1084 individual cases were treated, with 15 deaths (nine from pneumonia, five from malaria, and one from blackwater fever) At Serowe the returns show 158 Europeans treated, with two deaths, and 380 natives, with seven deaths At Ghanzi 313 cases were treated—57 Europeans and 256 natives, there were no deaths There is an all-round increase in the number of syphilitic cases treated

The Protectorate lies roughly between 2000 and 5000 feet above sea-level and only a few people live at the cooler altitudes of from 4000 to 5000 feet The portion of the country inhabited by the greater number of both Europeans and natives is adjacent to the only line of railway, which passes through the eastern side of the territory for a distance of 400 miles, the average altitude of the stations and sidings along this section of the line is 3418 feet The Protectorate has not been surveyed as a whole, but its area is estimated at 275,000 square miles The population at the last census was 152,983, of whom 1743 were whites, 52 Indians, 1003 coloured, and 150,185 natives

Nigeria

A report on the Colony and Protectorate of Nigeria for the year 1925 has been prepared by Mr H M-M Moore, principal assistant secretary The following is a summary of the medical section The health of the inhabitants of Nigeria cannot be said to have been good during 1925 The violence of epidemics of relapsing fever and cerebrospinal fever in the Northern Provinces was devastating in its effects in several areas and the death-roll has been enormous Relapsing fever had been severe in the north in 1924, and fears were then expressed that, owing to its method of propagation, extension would take place, these fears were fully justified The prophylaxis against these two diseases is simple, and propaganda might do much to mitigate the severity of the outbreaks In addition, the remedy for relapsing fever is almost a specific, and, where opportunity occurred to apply it, the death-rate among cases treated was reduced to 1 per cent Unfortunately, the aversion of the greater part of the population to European medicine is a heavy handicap Plague, though not assuming the alarming proportions of the outbreak in 1924, continued intermittently, and will probably not be eliminated from Lagos until the town has been replanned and to a large extent rebuilt A more serious feature was the extension of the disease to the mainland The possibility of this occurrence had always been foreseen, owing to the difficulty of controlling the canoe traffic with the mainland A small outbreak occurred at Agege in March, 10 cases being diagnosed while in August a considerable outbreak occurred in Ijebu-Ode district, there being over 500 cases, with 73 per cent mortality A smaller outbreak in November at Abeokuta, 100 per cent fatal, was directly traced to a child who was brought to Lagos, infected there, and returned by train Four medical officers were lent to augment the sanitary staff and all these outbreaks were got under control quickly, that at Ijebu-Ode being practically stamped out by November

For the first time since 1917 yellow fever made a demonstration in force, and a serious number of deaths of Europeans resulted It is probable that the concentration of sanitary effort on the combating of plague was partly responsible for the conditions leading to this outbreak An intensive antimosquito campaign has since reduced the stegomyia index to the lowest yet recorded in Lagos The Rockefeller Yellow Fever Commission is now established at Yaba, and is conducting researches at all the stations at which yellow fever occurred Small-pox frequently occurs in small outbreaks in all parts of Nigeria, but the extent of such outbreaks is becoming noticeably less year by year Vaccination continues to be actively pushed, and in two instances native administrations have adopted compulsory vaccination of infants Owing to improved methods of transport, the proportion of successful vaccinations has shown a striking improvement

The sanitary department has been strengthened by the addition of five medical officers of health, and the education of the inhabitants in hygienic rules and practice is proceeding with increasing vigour Preparations for a child welfare campaign have been made and will be vigorously carried out Two lady medical officers are making a commencement with instruction in obstetrics and the training of midwives, one at Lagos and the other at Abeokuta

Uganda

The territories comprising the Uganda Protectorate lie between the Belgian Congo, the Anglo-Egyptian Sudan, Kenya, and Tanganyika The Protectorate extends from one degree of south latitude to the northern limits of the navigable waters of the Victoria Nile at Nimule It is flanked on the east by the natural boundaries of Lake Rudolf, the river Turkwel, Mount Elgon (14,200 feet), and the Sci River, running into the north-eastern waters of Lake Victoria, whilst the outstanding features of the western side are the Nile watershed, Lake Albert, the river Semliki, the Ruwenzori Range (16,794 feet), and Lake Edward The population on 31st Dec, 1925, was estimated to be 3,148,481 —viz, 1703 Europeans, 9176 Asiatics, and 3,137,602 native inhabitants According to the latest annual report the country continues to prosper, but it is pointed out that Uganda is at present dependent almost entirely upon its cotton crop and that any set-back in its cultivation or marketing, therefore, would instantly be reflected in the trade of the country As a precaution against such a contingency natives are being encouraged to grow other economic crops upon which they may fall back in case of necessity The establishment of a labour department for the provision of labourers for Government departments, and the care of labourers throughout the Protectorate, has been justified The demands of all departments were met and the physical condition of the labourers themselves at the termination of their contracts amply proved, if such proof were needed, the wisdom of providing them with a well-balanced ration The activities of the medical department and the missions were extended during the year A decline in the total death-rate and an increase in the birth-rate were recorded, and the excess of births over deaths accounted for an increase of 12 917 in the native population The progressive manner in which such excesses have been maintained since 1921, when the total deaths exceeded the total births over the whole Protectorate, is very satisfactory An International Commission, with headquarters at Entebbe, was appointed by the League of Nations, to study scientific questions relating to sleeping sickness The climate of the Protectorate as a whole, though pleasant, cannot be considered healthy for Europeans European children as a rule thrive in infancy, but considerable risk is attached to bringing them out when they are 2 or 3 years old, as they are liable to attacks of malaria and the resultant anæmia The health of adults depends mainly on their mode of life, and, with care, constitutional health should not be impaired, but even if physical fitness is maintained the altitude and proximity to the Equator combine to produce nervous strain after prolonged residence Outdoor manual labour is dangerous for Europeans, and on plantations a manager's or owner's duties are for the most part supervisory The favourite localities for European plantations are the Buganda

Ealing Borough —Asst M O H £600

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Killin, Perthshire

The Secretary of State for the Home Department hereby gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for Selkirk County (Sheriffdom of Berwick, Roxburgh, and Selkirk) Applications should reach the Private Secretary, Scottish Office, not later than Feb 1st

Births, Marriages, and Deaths.

BIRTHS

COLVILLE —On Jan 5th at Glencairn, Oldfield road, Bath, the wife of Oliver Colville, M D, of a son

GIMLETTE —On Jan 7th at Wiesbaden, the wife of Captain G T Gimlette, R A M C, of a son

ROFFEY —On Jan 2nd at a London nursing home, the wife of Dr Bernard Wilson Roffey, of a son

MARRIAGES

BLAIR—BROWN —On Jan 8th, 1927, at St James's Church, Gerrard's Cross, by the Rev J M Glubb, M A, assisted by the Rev A Laws, Leslie George Blair, son of Mr and Mrs Charles J Blair of Birkenhead to Olive Stewart Brown, daughter of Mr and Mrs Robert Brown of Rosegarth, Gerrard's Cross

HANAFIN—SIDNEY —On Dec 21st, 1926, at Christ Church, Aden, Major John Berchmans Hanafin, C I E, I M S to Mary Rosamond, younger daughter of the late Mr and Mrs Marlow Sidney, of Blyth, Northumberland

WHITTICK—OBERFOELL —On Jan 7th, very quietly in London, F Percy Whittick, M.D, of Upper Brook street, W, to Johanna C Oberfoell, widow of Augustus Oberfoell, M D

DEATHS.

COLLIER —On Jan 4th, suddenly, at Woodstock-road, Oxford, Ivy Collier, M B, B S

DISMORR —On Jan 4th, at Purton, Wilts, Henry Bertram Dismorr, M R C S Eng, L R C P Lond, aged 49

FORBES —On Nov 24th, 1926, William Wood Forbes O B E, Major late R A M C, Director Quarantine Board of Egypt

GAITSKELL —On Jan 6th, at Wickhamway, Beckenham, Edward Forbes Gaitskell, M D (late of Sydenham), in his 88th year

HUTCHINSON —On Jan 6th very suddenly, at Maloja, Switzerland, Frederick Eric Arundel Stewart Hutchinson, M D, of Hove, aged 37

TWIGG —On Jan 6th, at Malahide, Co Dublin, Richard Crawford Twigg, M B, of Nightingale lane, Balham, S W, aged 62 years

WALLIS —On Jan 4th, C Edward Wallis, M R C S, L R C P, L D S, of Welbeck-street

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

THE DISPOSAL OF SEWAGE

ON Jan 3rd Dr W Butler and Mr J H Coste, F I.C., read a paper on Modern Methods of Sewage Disposal, before the Society of Chemical Industry Pointing out the limited value of sedimentation, they said that the time taken by very small particles in falling a useful distance may easily be too long for sedimentation in a channel which is not inordinately long and shallow Even if perfect sedimentation were possible the effluent obtained would contain organic matters in solution and would be putrescible, it would be unfit for discharge into a river unless the flow were many times greater than that of the effluent The addition of chemical precipitants merely causes coagulation of the suspended particles, and does not remove matters in true solution

After reference to the disadvantages of land treatment, they discussed the nature of the processes occurring in the intensive biological treatment of sewage The natural processes which are part of the life history of the varied flora and fauna of sewage are stimulated and accelerated, so that what takes days on land takes hours in a biological tank W J Dibdin utilised coke or some other surface as a nidus for the organisms The advance made by Mr G J Fowler and his associates lay in the fact that material was generated in the sewage itself by maintaining it for weeks in a state of agitation and aeration caused by blowing air through it The small quantities of activated sludge thus obtained are utilised for the treatment of more sewage, and by continued repetition sufficient material is obtained for large quantities of sewage to be converted in a few hours into a clear, bright fluid, having a slight earthy smell, relatively free from organic matter and with the original ammonia of the sewage replaced more or less completely by nitrates The increase in the bulk of the activated sludge obtained by repeated treatment shows that some of the organic matter of the sewage is removed as such, probably both by sedimentation of suspended matters and by precipitation of colloids, whilst the formation of nitrate shows that changes of an oxidative character also occur Experiments made by Dr Butler and Mr Coste with an air-blowing diffuser plant showed that much reduction takes place in the albuminoid ammonia The clarity of the effluent is markedly increased, and it is found to be stable for three days in an open vessel It is to be noted that practically no change occurs in the pH value When used for sedimented sewage in place of crude sewage the plant proved to be capable of dealing with four times the volume The effect of mechanical agitation with paddles was also tried and found to be satisfactory, both for crude and sedimented sewage Aeration tanks of the diffuser plant were later used in conjunction with the paddle plant for re-aeration of the sludge which had been found to be the essential part of the process The results of these experiments led them to the conclusion that for the combined aeration and agitation of activated sludge and sedimented sewage, agitation by mechanical means such as paddles and propellers is most suitable, but for regeneration of the activated sludge—in order to raise it to its highest pitch of activity—the diffusion of air by blowing best meets the requirements They are of opinion that where it has not been found necessary to adopt separate aeration of the returned sludge only, the mixture of sewage and sludge has been allowed to remain in the treatment tanks for an unnecessarily long time in order than this aeration may be effected "It is surely better in every way to use treatment tanks to their full capacity for the preparation of an effluent and to restore the impaired activity of the relatively small volume of sludge by a separate treatment in a tank or tanks of suitable capacity"

Experiments made showed that the composition of a mixture of activated sludge and sewage does not alter appreciably during five hours when submitted to agitation without aeration, air is therefore a necessary factor in the process That the air acts as an oxidising agent was shown by analysis of the air above activated sludge and mixtures of activated sludge and sewage, placed in bottles, when oxygen was found to be absorbed and carbon dioxide produced An immediate change occurs, practically at the moment of mixing, when activated sludge is added to sewage, this is shown by the amount of oxygen absorbed from permanganate in four hours being invariably less than that which is theoretically calculated for the constituent liquids

Dr Butler and Mr Coste have made experiments which, they consider, show clearly that all the useful action of activated sludge is associated with the moist solid and not with the liquid portion

A Lecture
ON
ANÆSTHETICS

Delivered to Practitioners attending the Post-Graduate Course at Aberdeen

BY J ROSS MACKENZIE, MD ABERD,
ANÆSTHETIST AND LECTURER ON ANÆSTHETICS, ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN, ASST ANÆSTHETIST, ABERDEEN ROYAL INFIRMARY

ANÆSTHETICS are of importance to the practitioner and his patients from three points of view (1) where the patient is sent to hospital or to a nursing home and the practitioner is not the anæsthetist, (2) where the surgeon comes to the patient at home, or to the cottage hospital, to operate and the practitioner gives the anæsthetic, (3) where the practitioner gives the anæsthetic and performs the operation

There are several factors which modify general anæsthesia no matter by whom it is administered (1) the preparation of the patient, (2) the psychic element in the patient, (3) the choice of the anæsthetic agent, (4) the combination of oxygen and carbon dioxide with the anæsthetic agent

PREPARATION OF THE PATIENT

These factors are more or less intimately bound together The patient should be neither starved nor purged Light, liquid diet may be continued in adults to within four hours of the operation, and in children and infants three and two hours It is important to the patient's safety that there should be no solid food in the stomach when he comes to the operation table Adult patients should have a teaspoonful of glucose or a lump of cane sugar three times a day, children may have barley sugar to suck ad lib, and infants frequent sips of sweetened water This should, if possible, be continued for several days prior to operation A simple aperient is best given two days prior to operation so as to ensure an evacuation of the bowel, but nothing more Frequent drinks of water containing 10 to 20 gr of bicarbonate of soda to the ounce increase the patient's blood alkaline reserve

What is the importance of these measures? Normally there is present in the blood a certain percentage of sugar and this blood-sugar is absorbed by the tissues In the normal metabolism of fats we get carbon dioxide, water, and heat, but under certain conditions, one of which is a deficiency of sugar in the blood, fats are broken up into oxybutyric acid and diacetic acid, with acetone as a by-product The chief causes of hypoglycæmia are starvation, vomiting, purging, and sepsis

So that in the interests of the patient we avoid any semblance of starvation, purgation, or enemata, and give plenty of sugar and alkalis both before and after operation Such a régime protects the patient against the tendency to perverted or incomplete metabolism, which may be the main cause of (*a*) post-anæsthetic acidosis, (*b*) post-anæsthetic vomiting and nausea, or (*c*) delays or prevents the return of the vital cells of the body to their normal function

THE PSYCHIC ELEMENT IN THE PATIENT

The psychic effect upon the patient of an impending operation and of losing consciousness in anæsthesia is usually underestimated Dread of the anæsthetic, often too well concealed is the arch-enemy of the anæsthetist and frequently banishes both appetite and sleep It affects adversely the stability of the nervous system, especially the vital medullary centres, and is expressed by palpitation, rapid pulse, pallor, and dilated pupils

Why is it that patients take anæsthetics so well in obstetric practice? Most practitioners use chloroform for this class of work and almost invariably find that the patient takes it well and requires very little The explanation lies in the psychic condition of the patient. In surgery the anxiety of patients arises partly from fear that they will not wake out of the anæsthetic or that the surgeon may commence before they are properly asleep, and partly from dread of what may be found at the operation and whether they will recover This anxiety may have continued for days and progressively increased to a maximum in the anæsthetic room Here the mental condition of the patient is found to be highly detrimental to the safe induction and maintenance of anæsthesia In obstetrics the opposite condition prevails, the patient's mental anxiety arises from fear that she will not get an anæsthetic, it completely passes as soon as the chloroform bottle appears and she is confident, not only that she will waken, but that when she does her troubles will be over

Prophylactic Measures—The anæsthetist should examine the patient before the operation, partly to assure himself of the patient's physical fitness and partly to assure the patient that he is in good form to take the anæsthetic This is sound practice and highly beneficial to the patient, even if a consulting physician has already sanctioned the anæsthetic An optimistic bearing on the part of the anæsthetist, even in the direst circumstances, gives some confidence to the patient Adults receive 7 gr of veronal the night before operation to ensure a good sleep, children have 10 to 15 gr of ammonium bromide by the mouth Morphine is a respiratory depressant and has a tendency to cause post-anæsthetic sickness and nausea, but it is a great boon to the patient, making him drowsy and largely indifferent to his unusual surroundings Except where chloroform is the anæsthetic of choice adults have a hypodermic of 1/6 gr of morphine and 1/100 gr of atropine three-quarters of an hour before operation; children under 12 years should not have morphine but require a hypodermic of atropine three-quarters of an hour before operation In the Children's Hospital babies get 1/200 gr, between 1 and 6 years 1/150 gr, and over 6 years 1/100 gr Atropine is a very valuable adjunct to anæsthesia In the case of ether it controls the secretion of mucus and prevents, water-logging of the respiratory tubes, excessive movement of the abdominal muscles, and the extraordinary muscles of respiration, with cyanosis and noisy inefficient anæsthesia It diminishes the risk of post-anæsthetic respiratory complications Atropine is also useful in chloroform anæsthesia since for any reason a change over to ether may become necessary

Some physiologists and anæsthetists believe that atropine prevents undue excitability of the vagus centre in the medulla, and thus controls the passage through the vagus nerves of reflex stimuli which otherwise might produce inhibition of the heart's action It is not convenient for the practitioner to arrive three-quarters of an hour before operation to give such a hypodermic, but the same dose dissolved in water may be given by the mouth the night before and repeated one and a half hours before operation with equally beneficial results, this can be carried out by the mother

Let me put here a plea for the presence of the practitioner at the operation in hospital or nursing home That is not always easy, but the beneficial effect on the patient's equanimity from the anæsthetic point of view is very important Further, first-hand information is available of the surgical condition of the patient, as well as of the surgical measures taken to remedy it

THE CHOICE OF THE ANÆSTHETIC AGENT.

A proper appreciation of the importance to the patient and to good anæsthesia of a well-considered anæsthetic agent is difficult to acquire The tendency to follow a more or less stereotyped routine in every case—chloroform, ether, or even gas and oxygen—is quite wrong The anæsthetist, whether practitioner or specialist, can arrive at a proper conclusion as to what agent will be most suitable only by making a preliminary visit to the patient and deciding upon the merits of the individual case. This visit makes

Province, the Toro district of the Western Province, and the Bunyora district of the Northern Province Meteorological statistics taken at Entebbe give the following results Average rainfall for the last 30 years, 58 88 inches Average temperature for the last 21 years, maximum, 78 10° F, minimum, 62 70° F Mean daily sunshine, 5 hours 12 minutes

BERMUDA

Mr John Trimingham, Colonial Secretary, in his report for 1925, gives the estimated civil population as 27,711 Including naval personnel and tourists the total would be estimated at 30,157 The number of living births registered was 388 males (117 white and 271 coloured) and 359 females (106 white and 253 coloured) The living birth-rate among the civilian population was 20 9 per 1000, being 16 3 amongst white and 37 1 among the coloured population The total rate, including still-births, was 27 9 per 1000 The number of illegitimate births, including still-births, numbered 151 out of 753 civilian births, equivalent to the rate of 20 1 per cent (white 3 8 coloured 26 6) The death-rate was 7 01 per 1000 for the white and 16 7 for the coloured population The general health of the community was good The number of cases of infectious diseases reported were as follows Scarlet fever, 2, typhoid fever, 28, paratyphoid, 1, measles, 3, chicken-pox, 20, diphtheria, 17, tuberculosis, 3, leprosy, 1, pneumonia, 2, ophthalmia neonatorum, 1, cerebro-spinal meningitis, 1, erysipelas, 3, total 82, as compared with 211 in 1924 and 130 in 1923

The King Edward VII Memorial Hospital, to which no reference has hitherto been made in the annual reports, was opened in July, 1920, the progress of construction work having been made during the years of the war Its management is under the direction of a board of governors, and the direct management is under the direction of the medical superintendent The nursing staff consists of a matron, five sisters, about 12 nurses, and a number of pupil nurses and probationers The number of "free" cases treated in hospital during 1925 was 14 the number of cases exempted by law from payment of hospital fees was five 164 maternity cases were treated (white 151, coloured 13) The general average stay of all patients in the hospital was 19 76 days Ninety-seven X ray examinations were made during the year

A NEW LONDON WEEKLY

WE have received the first two issues of a weekly paper, edited by Dr L Haden Guest, M P The *London Weekly* is published at *6d* by the *Commonwealth Review*, Ltd, whose directors are Lord Apsley (the Editor), Mr L St Clare Grondona, Lieut-Colonel G S Hutchison, and Mr F L McDougall The intention of the paper, as set out by the Editor in the first issue, is to popularise knowledge of empire affairs by taking, not a theoretical interest in political or economical speculation, but a practical interest in helping the people to a happier individual and social position Among the contributors to these first numbers are Mr L S Amery, Secretary of State for Dominion Affairs and the Colonies, Dr Walter Elliot, Parliamentary Under-Secretary for Scotland, and Mr Philip Snowden A valuable feature of the paper will be a financial survey contributed by Mr William Graham, M P, late Financial Secretary to the Treasury The second issue commences a series of articles entitled "Careers in the Overseas Empire," an editorial assurance being given that these articles will be contributed by writers of experience and authority, dealing with particular fields available in the Overseas Empire for British migrants The first article in this series is contributed by Miss Florence Low, who deals with Canada as a field for British teachers

THE DAKOL DAYLIGHT SCREEN

A RECENT article in THE LANCET (1926, ii, 1251) on Light and Typesetting prompts a notice of a translucent colour screen, designed to produce a close approximation to daylight when used in conjunction with metallic filament lamps of the half-watt type The Dakol Daylight Screen consists of a glass screen, clear blue in colour, mounted in contact with a special diffusing screen Owing to the high percentage of light transmitted, the resulting illumination is much stronger than that produced by some other daylight lamps for the same consumption of electrical energy After a few minutes in a room lit with Dakol-screened lights it becomes impossible to distinguish by eye the blue colour of the screen, which now appears perfectly white It was only in comparison with the ordinary yellow unscreened artificial light that the new light now seems blue in shade There is no doubt th[illegible]cial daylight has a great future in industry, actu[illegible] have already shown a smaller percentage of mistakes and breakages in workshops and offices where this system has been installed, and as the advantages become recognised it will be more widely used in clinical and diagnostic work The essential points of such illumination are, first, light of the right colour-distribution and, secondly, a sufficient intensity of that light The essential colour correction has often been obtained by the use of screens which absorb a high proportion of the incident light In such cases the full advantages of artificial daylight have been missed by an attempt to work with too dim a light The Dakol screen is placed on the market by the L H M Engineering Co, Ltd, 17, Dartmouth-street Westminster

THE THERMIX FLAMELESS HEATER

THE principle on which this heater works is that of catalysis The vapour of aviation or No 1 petrol combines with the oxygen of the air in the presence of the active catalytic reagent platinum black The platinum black does not take part in the reaction and hence is not used up in any way The only precaution that is necessary is the use of the spirit specified, as catalytic agents are readily "poisoned" as it is termed in industrial chemistry The catalyst loses its activity, not by chemical action but by the active surface becoming clogged with solid particles and impurities, hence the necessity for the purest spirit There should be many applications for this useful piece of apparatus In particular, when electricity and gas are unavailable, the steady source of heat without fume, smoke or danger of fire, might prove invaluable The safety of the heater is due to the fact that the actual temperature at which the combustion takes place is much lower than that at which petrol vapour ignites in the absence of platinum black Hence, though a plentiful supply of heat is produced, the source is not raised to a high temperature as in an ordinary stove The makers are Frederick Pollard and Co (Bearings), Ltd, Nottingham-road, Leicester

A LINK WITH THE PAST

A CORRESPONDENT sends us the following note from a hospital in Birmingham —

E B came under my observation on the night of Dec 26th, 1926, with a strangulated subumbilical incisional hernia The skin overlying the swelling was necrotic in places, and she vomited several times At operation the sac was found to contain a loop of completely gangrenous intestine, which had perforated The loop was resected and the ends anastomosed Contrary to expectation, she is recovering The interesting feature of this case is that her original operation of ovariotomy was performed on July 3rd, 1888, by Lawson Tait We thus have a follow-up of nearly 40 years

CHRISTMAS POEMS

Dr Herbert A Smith, of 1, Denbigh-road, Ealing, W 13, has sent us a copy of a collection of verse which he is selling at 2*s* 6*d* a copy, the money being forwarded to the reconstruction fund of the Middlesex Hospital The eight-page book is bound like a Christmas card, is prettily illustrated, and contains verses in many varieties of metre all infused with deep religious sentiment

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 1ST, 1927

Notifications—The following cases of infectious disease were notified during the week—Small-pox, 342 (last week 302), scarlet fever, 1017, diphtheria, 961, enteric fever, 31, pneumonia, 1514, puerperal fever, 44, puerperal pyrexia, 122, cerebro-spinal fever, 8, acute poliomyelitis, 14, encephalitis lethargica, 40, dysentery, 4, ophthalmia neonatorum, 114 There was no case of cholera, plague, or typhus fever notified during the week

Deaths—In the aggregate of great towns, including London there was no death from small-pox, 2 (1) from enteric fever, 36 (0) from measles, 2 (2) from scarlet fever, 52 (18) from whooping-cough, 51 (19) from diphtheria 61 (10) from diarrhœa and enteritis under 2 years, and 86 (17) from influenza The figures in parentheses are those for London itself

Tuesday's radio bulletin contained the following item from the Ministry of Health in London "Incidence and mortality of influenza normal for the time of year"

SMALL-POX IN YORKSHIRE—Nearly 10 cases of small-pox have been reported in Sheffield during the present week, and the medical officer of health, Dr F E Wynne, is quoted in the press as saying that he greatly fears that the disease may resume its original virulence, and that several patients are suffering from disfigurement which he fears will be permanent The policy of isolating contacts has hitherto been pursued, but the epidemic has now reached the stage at which it is impossible to remove all the contacts and some will have to be isolated in their own homes Similar anxiety is attributed to Dr J J Huey, medical officer of health for Mexborough, who is said to have described the type of small-pox in that place as becoming more dangerous

1. Ether is highly irritant to the respiratory passages and must be given at first in minute doses so as to get the pharynx, larynx, trachea, and bronchi anæsthetised locally In the first stage of induction with ether the less hurry the more speed, and neglect of this fact may produce cough, respiratory spasm, and cyanosis

2 As soon as the patient is breathing easily and regularly continue a steady drop of ether on the mask To produce surgical anæsthesia the entire volume of respiration must pass through the ether-laden gauze The concentration of ether required for surgical anæsthesia in adult males is from 15 to 18 per cent and its extreme volatility makes this difficult to attain with an open apparatus

3 A clear airway is absolutely essential for ether anæsthesia

Spasm of the masseter muscles may occur during induction and is best anticipated by putting in a gag or a dental prop before commencing The tongue may fall back and partially occlude the airway In such case the artificial airway will not only support the tongue but ensure a clear airway Mucous secretion may collect in the pharynx, larynx and trachea, this is a very disturbing condition both to the surgeon and anæsthetist and should never arise Atropine prevents the stimulation of the secretory glands by ether, and if it has not been given or has not taken effect another dose should be given upon the table, the condition meanwhile being relieved by turning the head to the side so that mucus collects in the dependent cheek Owing to relaxation of muscles the lower jaw may fall back and partially occlude the airway Support with one finger at the angle of the jaw will be necessary.

4 Ether first stimulates the respiratory centre and then depresses it Deep respiratory movements, such as take place in ether anæsthesia during both the induction and maintenance, may cause the loss by expiration of more carbon dioxide than is being produced by the metabolism The normal hormone of the respiratory centre is carbon dioxide If it is blown away by deep respiration a period of apnœa arises and may continue for 30, 60, or 90 seconds It is a rather alarming experience to the inexperienced that the respiration should become shallow and then cease. In such circumstances remove the mask and satisfy yourself that the circulation is normal If normal you may wait with equanimity, since the patient's metabolism will gradually produce sufficient carbon dioxide or other acid from deficiency of oxygen and incomplete metabolism to stimulate the respiratory centre and the respiratory cycle will commence again

The immediate risk is probably ten times greater with chloroform than with ether This does not take account however, of the remote risk with ether

ETHYL CHLORIDE—ETHER ANÆSTHESIA

Open ethyl chloride is a very convenient method of induction It is portable, easy to the patient, rapid in action, and safer than chloroform In adults the same arrangements as for open ether are made Instead of commencing with ether one sprays 3 c cm of ethyl chloride on the mask, and as soon as respiration is active drop ether upon the mask and continue until surgical anæsthesia is complete

In children spray 1 to 1½ c cm of ethyl chloride upon the Yankauer mask and drop ether slowly upon the mask One minute later spray another 1 to 1½ c cm of ethyl chloride upon the mask and continue with ether There is a considerable tendency to respiratory and masseter spasm with ethyl chloride For that reason a dental prop or a gag in the mouth before starting the anæsthesia may be of great assistance Stertorous respiration is the best indication of surgical anæsthesia with ethyl chloride. This sign is less evident with ethyl chloride and ether

It is a very valuable anæsthetic for enucleation of tonsils, circumcision or other minor operation, as well as for major operations

Mixtures of chloroform and ether are not to be recommended because the stimulating action of ether upon the respiration may cause the inhalation of doses of chloroform, the effects of which are very difficult either to anticipate or measure Induction with chloroform and maintenance with ether is a good method of anæsthesia for children In enucleation of tonsils where chloroform is the anæsthetic it is good practice to complete the induction with ether because it is safer to the patient and gives 30 seconds more time for the surgeon's work.

LOCAL INFILTRATION ANALGESIA

This is a method of infiltrating the skin and deeper tissues with a ½ or 1 per cent novocaine solution containing five drops of 1 in 1000 adrenalin to the ounce of novocaine The sensory nerves within the area of infiltration are anæsthetised and do not conduct any painful stimuli to the brain. It is a method which should be of considerable value to the practitioner, since with its aid he may painlessly remove cysts, open abscesses and perform other minor operations in his consulting room or in the patient's home

Novocaine is safe, non-irritating, very reliable, and several ounces of a ½ per cent solution may be infiltrated without in any way prejudicing the healing of the tissues The actual technique of the injection is simple An all metal syringe with various needles is required Commence your infiltration of the skin with a short, sharp needle, raising a wheal three-quarters to one inch in diameter, the only pain the patient should feel is the prick of the skin It is possible to infiltrate the operation area by extensions from the wheal Analgesia is complete in about 10 minutes, and its duration up to 90 minutes The adrenalin added to the novocaine solution is sufficient to render the operation area in some degree hæmostatic

In general anæsthesia, especially gas and oxygen, local infiltration of the operation area with novocaine is very important Under general anæsthesia the patient does not feel pain, but his brain is profoundly affected by the repeated sensory impulses which reach it by cutting, tearing, or stretching of the tissues. These sensory impulses are a considerable factor in the production of surgical shock and without doubt a method of preserving the patient's nerve vitality upon the operation table is to block the sensory nerves in the operation area

An Address

ON

THE NEED FOR MEDICAL TEACHING ON BIRTH CONTROL.

Delivered before the Manchester Medico-Chirurgical Society on Jan. 12th

BY ARTHUR E GILES, M D, B Sc,
M.R C P LOND, F R C S EDIN,
CONSULTING SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN AND GYNÆCOLOGIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM

AUTHORITATIVE teaching on the subject of birth control, or, to be more precise, conception control, is required for two reasons In the first place such control is necessary in many cases within limits which I shall try to define; and in the second place, the general public already knows a good deal about it, and is anxious to know more Instruction should be given by medical men They are in a position to judge of the necessity for control on medical grounds and its advisability for economic reasons, moreover—and this is equally important—they can appreciate the conditions in which control is harmful medically or inadvisable ethically They can also give information as to the best means to be employed in individual cases

For want of proper teaching the public has had to go to popular books, some of which, written in an a pleasant impression upon the patient. It gives the assurance that every precaution is being taken for his safety and comfort, relieves the mental agony of the approaching ordeal, and provides against patient and anæsthetist being strangers when they meet in the anæsthetic room

There are three principles which govern the choice of an anæsthetic

1 The safety of the patient This includes the immediate risk upon the table and the remote risk from post-anæsthetic complications Gas and oxygen[1] is the safest anæsthetic agent, but its safety is largely dependent upon the type of patient, the surgeon who is to operate, and the experience of the anæsthetist Open or perhalation ether comes next, but where there is any bronchitis or emphysema, or tendency to respiratory spasm, chloroform will not only be easier but safer to the patient

2 It must provide an efficient anæsthesia for the surgical work on hand In enucleation of tonsils, for example, the anæsthesia should continue for the duration of the operation, neither more nor less In circumcision the anæsthesia should be deep enough to avoid reflexes reaching the medullary centres on clamping or cutting the redundant prepuce

3 It ought to have the approval of the surgeon who is to operate Cooperation between the surgeon and the anæsthetist is as essential in the nursing home as in the patient's home and the cottage hospital There are few anæsthetists, whether practitioner or specialist, who can afford in the interests of the patient to be arrogant or quietly ignore the experience of the surgeon as to what anæsthetic is likely to prove most efficient for the patient and the task on hand

The choice having been made, the anæsthetist's duty is to see that his anæsthetic table contains everything he may want in any emergency, to induce and maintain surgical anæsthesia, to keep the airway clear and to watch with much diligence and constancy the effect of the anæsthetic upon the patient It may appear a refinement of anæsthesia to mention the inclusion of a cylinder of oxygen in your armamentarium, but no operating theatre, not even an improvised operating theatre, is complete without oxygen at hand and, one might add, of equal importance, at least to the patient, a cylinder of carbon dioxide

Gas, Oxygen, Carbon Dioxide, Ether Anæsthesia with De-etherisation

The ideal anæsthesia is one which will temporarily inhibit the function of the cortical brain cells and break the sensory reflex arc without affecting the functions of the organs or causing damage to the tissue cells, and whose action ceases with the administration Gas, oxygen, carbon dioxide, ether anæsthesia with local or regional analgesia and de-etherisation is the nearest approach we have to the ideal at present It is almost completely reversible, highly evanescent in action, and leaves few traces of disturbance in the normal functions of the organism Unfortunately, this type of anæsthesia requires an expensive and complicated apparatus, together with a considerable experience of an exacting technique for safe and successful administration

There are three anæsthetic agents well suited to the practitioner who is giving an anæsthetic occasionally, and they have the three-fold merit of (a) portability (b) requiring no complicated apparatus, (c) providing surgical anæsthesia for almost any emergency They are chloroform, ether, and ethyl chloride, with combinations such as chloroform followed by ether or ethyl chloride and ether

Chloroform Anæsthesia

Chloroform is a protoplasmic poison and is, therefore, a potent and dangerous narcotic agent which ought to be used for anæsthesia always with knowledge, caution, and must respect

Several principles are constantly involved in its safe administration

1 Free dilution of the vapour with atmospheric air For this purpose an ordinary linen towel is much better than a mask It should be held over the patient's face as a dome with the edges hanging free, chloroform is then allowed to drop on to the centre of the dome at a rate such as can be easily counted. Theoretically one should begin with 0 1 per cent vapour and steadily increase up to 2 per cent , the increased percentage is got partly by increasing the rate of the drop, but much more by increasing the area over which one is dropping the agent When the induction of anæsthesia is complete, reduce the rate of dropping and maintain anæsthesia by supplying as much as is being lost by expiration This will probably mean that throughout the operation 0 5 to 1 per cent of chloroform will be sufficient During the administration of chloroform the anæsthetist should be calculating in fractions of per cent its effect upon the patient

2 The second principle is a complete absence of intermittency in the administration Intermittency, particularly during the induction, is probably the greatest single factor of danger in chloroform anæsthesia A slow steady drop, gradually increasing the area over which you drop, is continued without a break other than to note the progress of induction until surgical anæsthesia is complete

3. The third principle is a proper appreciation of the fact that the induction is the most dangerous period of the anæsthesia Early in the induction of anæsthesia with chloroform the vagus centre in the medulla becomes extremely sensitive, and any reflexes passing from the operation area tend to cause the passage of stimuli through the vagus nerves to the heart, resulting in inhibition of the heart's action

There are three conditions in which reflex stimuli are especially liable to produce this effect upon the heart (a) during excitement and struggling, (b) interference with the patient during light chloroform anæsthesia, (c) status lymphaticus, or where there is an excess of lymphoid tissue This irritability of the vagus centre passes away when surgical anæsthesia is complete

The earliest sign of overdose with chloroform is shallow respiration due to depression of the respiratory centre and should attract attention at once If noticed in time it will be sufficient to withdraw the anæsthetic and permit free ventilation with air or oxygen

Infants and children take chloroform well They go slowly through the greater part of the induction, then pass rapidly to surgical anæsthesia, and as rapidly into the danger zone Children require very little anæsthetic for the maintenance of surgical anæsthesia and are readily overdosed Babies often scream, and you are safe in dropping chloroform on a towel over the face until the crying ceases and then continue with ether Children are frequently terror stricken and the resulting psychic shock adds very materially to the danger of the anæsthetic Infants and children tend to go to sleep early in the induction of chloroform anæsthesia, and the tidal exchange of air is so small that they only take in enough to keep them asleep The respiration being quiet and regular and the corneal reflex absent, one is liable to conclude that they are in a state of surgical anæsthesia, but a towel-clip or a skin incision will produce a scene which ill-becomes and properly upsets the anæsthetist's dignity If you have any doubt sharply pull up the mentum or push forward the angle of the jaw or pour on some ether, and your doubts will vanish Infants or children showing any evidence of anæmia, or sepsis or shock should not, under any circumstances, be anæsthetised with chloroform

Ether Anæsthesia

Ether may be administered to infants and children upon a linen towel, but a vankauer mask covered with a few layers of gauze is better A layer of cotton-wool with a hole for the mouth and nose should cover the area of the face pressed upon by the mask In adults an Ogston[2] mask is by far the most satisfactory method of producing perhalation ether anæsthesia and it is a drawback, not unattended by risk, for the woman to have to get up out of a warm bed in order to use a douche

---

[2] Ogston Brit Jour of Anæsthesia, October, 1924, p 76

6 *Surgical Methods*.—The vasa deferentia may be cut and tied in the man, or the Fallopian tubes in the woman. Cases of performance of the operation on the man are very rare: and in the case of women it is hardly justifiable to perform an operation for this purpose alone But when an operation is necessary for some other reason it is a proper and legitimate procedure to divide the tubes at the same time. There are various ways of doing this: the method that I adopt is to divide the tube and overlap the two ends about an inch, tying a ligature round both at each end of the overlapping portion

DRAWBACKS IN PRINCIPLE TO BIRTH CONTROL.

There are drawbacks to birth control on public as well as on personal grounds. A detailed examination of the public grounds would carry me too far into the Malthusian doctrines and I will dwell on one point only—namely the disadvantages to a country that result from a falling birth-rate. It is said on the other side that there is neither work nor food enough for all, and that the proper remedy is to limit the number of future wage-earners and food-consumers My own view is that the fault is due to the conditions of work and not to the numbers and that altered conditions would provide work enough for all the unemployed in the country. If birth control could ensure the elimination only of the unfit, the wasters and the degenerates, something might be said for it. But on the contrary, those who are least likely to breed valuable citizens are also the least likely to take any steps in the matter Restriction is more practised by thoughtful and efficient parents, whose offspring might well be of the greatest service to the community

Then there is the personal side, and here I am not concerned with cases of restrictive methods adopted after several children have been born. But I am deeply concerned with restrictions adopted at the beginning of married life. The immediat eeffect is to foster selfishness and self-indulgence in the married couple and to rob the early married life of much of its proper romance. The later effects are not invariable, but I have met many instances of people who have avoided the possibility of childbearing in the early years and later on, when they have changed their mind and thought that they would like to have children, they have not been able to do so I do not know how this has come about in individual cases. It may be through some change in endocrine activities, due to distortion of the normal sex-act. In some cases it may be due to the method employed, for I have long been convinced that the prolonged use of quinine pessaries may have this effect. However it may be, there is no doubt about the unhappiness and the disappointment, the regrets and mutual recriminations and sometimes even the permanent estrangement and separation that the later years of married life may enfold

Another late result is the physical one. Repeated sex-stimulus in early married life without the physiological rest and outlet provided by pregnancy predisposes to hyperplasia, chronic congestion and the development of uterine fibroids.

DRAWBACKS INHERENT IN CERTAIN METHODS

The least harmful plan is undoubtedly the restriction of intercourse to the so-called safe period Of mechanical means the condom is probably the least objectionable. Coitus interruptus has a bad effect on the woman's health in many cases. I have spoken of the possible effect of quinine pessaries in leading to permanent sterility. Some of the so-called check pessaries may set up an ascending metritis and salpingitis when used by careless and ignorant women.

CONCLUSION

Birth control is a necessity on medical grounds in certain circumstances and it is expedient on economic grounds in a few cases. The medical profession should lay down its indications and point out its limitations. To those who wish to practise it for economic reasons its risks and drawbacks, immediate and remote, should be pointed out: and when it is necessary, the best method to be adopted in each individual case should be explained

SPECIFIC STIMULATION THERAPY AND PROTECTIVE INOCULATION IN TUBERCULOSIS.*

BY GEORG SCHRÖDER, M D.,
MEDICAL DIRECTOR OF THE NEW SANATORIUM, SCHÖMBERG, NEAR WILDBAD, GERMANY.

THIRTY-FIVE years have passed since the discovery of tuberculin by Robert Koch and in this long period many investigators have worked at the problem of specific treatment, without finding—it must be confessed—any firm basis for this difficult department of knowledge. I have myself tested most of the so-called specific remedies for tuberculosis on a large number of patients during the last 30 years without finding any specific that can be absolutely relied upon for treatment or for prophylaxis. At the same time we all know that there are remedies derived from the bacillus which have a specific action upon the foci of disease To these the tuberculous patient is quite remarkably sensitive. They all have the power of promoting the formation of tuberculous tissue

This pronounced sensitiveness of the affected organism towards tuberculin preparations consists in an increased tendency to inflammation. We know now that a number of other substances such as protein bodies, chemotherapeutic remedies, metallic salts arsenic, are able to start distinctly more active inflammatory changes in the tuberculous than in the healthy Here must be included radiotherapy, and to a considerable extent all our general remedies.

And yet we are concerned in these non-specific stimulants with something quite distinct from the specific ones obtained from the bacillus. The latter act in extremely small doses and are able (as already stated) to start the formation of tuberculous tissue. On these two points rest the only certain facts that we know about the specific action of the above-mentioned preparations

Theories of Mode of Action of Tuberculin.

Many theories have been formed to explain the mode of action of tuberculin. They were originally based upon the supposition that it was a true antigen, that the antibodies which we find in the blood of the tuberculous have a direct connexion with the antigens, and that the action of tuberculins must be explained as a form of antigen-antibody formation in the sense of Ehrlich's theory. These notions have all suffered shipwreck. It would take me too far to go into details; but we know now that the tuberculins are not immunising remedies and that they cannot be regarded as true antigens. The theory of Bessau which assumes that the sensitiveness to tuberculin depends on the formation of so-called tuberculocytes through stimulation of the mesenchymatous tissues, is suggestive. According to Bessau, the result is the accelerated formation of stronger tuberculous tissues. Selters's explanation is however, more in accord with the facts as known to-day. According to him tuberculin is an irritant which causes inflammation of tuberculous tissue without being altered or bound up therewith

Feldt and I have proved that the natural disintegration of the focus of disease is accelerated through stimulation by the so-called specifics The toxins arising from the disintegrated tissues and bacteria bring about the general and focal reactions by means of the sympatheticotonic nervous system and the erotic vein, with insufficient knowledge, and with a marked bias, are liable to do a good deal of harm Those who have not had access to books, as well as some who have, have resorted to some so-called birth control clinics staffed by non-medical persons who advise the use of appliances without selection of suitable cases or discrimination as to the means to be employed In these two pictures, of the medical and the popular expositions of the subject, we have an epitome of the use and the abuse of teaching about birth control

---

*A paper read at the Joint Meeting of the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions, Nov 22nd, 1926

MEDICAL GROUNDS FOR BIRTH CONTROL

I may say that I make use of the term birth control here because it is simple and generally understood Strictly, it would include prevention of birth by the induction of abortion, but this, of course, we are not considering, as we are dealing only with the prevention of conception

1 *Heritable Disease in Either Parent* —Here we have to consider syphilis, tuberculosis, and mental disease Syphilis is, of course, curable, and once cured it ceases to be heritable But as long as there are positive signs in either parent there is no doubt that the begetting of children should not be allowed. Tuberculosis should be regarded in the same way, though it is the tendency to the disease that is inherited rather than the disease itself With mental disease it is a question of degree Obviously, lunatics and imbeciles should not be allowed to have children, but the minor forms of mental instability are often so closely allied to genius that if such people were prevented from having children the loss might outweight the gain

2 *Diseases that make Childbearing Dangerous to the Mother* —In this category we may include some forms of heart disease, tuberculosis, and nephritis Each case must be considered on its merits, but it is a canon of medical practice that the mother's safety has priority over the unborn child, and à fortiori, over the unbegotten child In some cases the restriction need be only temporary and can be removed if the disease concerned clears up

3 *Conditions that would Obstruct Labour* —These include contraction of the pelvis, or the presence of a tumour or other abnormality If the obstruction be removable, as in the case of a tumour, it is right to prevent conception until this has been done , but if it be permanent, as in the case of a contracted pelvis, the patient has the right to choose whether she will take the chance of pregnancy with a view to delivery by Cæsarean section, or whether she shall be exempted from pregnancy by the adoption of preventive methods

4 *Previous Difficulty or Dangerous Deliveries* —When a woman has passed through a difficult or dangerous confinement, I hold that she has the right to say that she will not face the ordeal again, even though the complications may have been of a type unlikely to recur Some women, with an ardent desire for another baby, might be willing to take the risk With others, the prospect of another such experience would entail intense mental suffering and might easily cause a mental breakdown

5 *Childbearing in Excess of a Woman's Strength* —There is no doubt that many women have borne large families with only short intervals between successive confinements, and have appeared to be none the worse for it But with many it is different, and a succession of children close together has left them physical wrecks It is not only permissible, but necessary, for medical men to advise preventive methods in such cases, in order that pregnancies may be both spaced out and reduced in number And if a woman asks for help in such circumstances, I consider that she is entitled to receive it

ECONOMIC GROUNDS FOR BIRTH CONTROL

When we come to consider the economic grounds for birth control, ethical and sociological considerations overshadow the medical, and we find widely divergent positions taken up by thoughtful and conscientious persons The ardent followers of Malthus adduce many reasons why the population should be held in check In my opinion their concentration on abstract generalities places their vision out of focus for attention to the individual human side of the matter, which is at least as important At the other extreme, some religious bodies, such as the Roman Catholic Church denounce birth control in principle and can see no exceptions where it is desirable, save that they will rather unwillingly concede that there may be something to be said on medical grounds My position is intermediate, I recognise that birth control is a contravention of natural law, and that such contravention can seldom be carried out with impunity But facts must be faced, and there are cases where the penalty of compliance with natural law is greater than that of defiance of it But if my position is intermediate, I must frankly confess that it is much nearer to the extreme of prohibition than to that of wide adoption

The plea that a couple cannot afford to have more children is one that I should admit as a permissible reason for birth control This presumes that they have one or more already Moreover, the poor drudge of a working woman whose babies keep on coming, so that childbearing and ceaseless toil make up her whole existence, deserves our pity and our help, and the resources of medicine should be applied to the limitation of her family But I should not admit that it is right for people to begin married life by practising birth control. If they cannot afford to have one child, they cannot afford to get married And if the reason given is that they want to enjoy themselves and have a good time without the responsibilities of parenthood, I should say that the reason is an unworthy one Let such people enjoy themselves and have a good time, and wait to get married until they have acquired enough unselfishness and seriousness of character to accept the normal responsibilities of married life

METHODS ADOPTED

1 *Abstinence* —As a temporary measure this is reasonable, but for adoption during a considerable period it is not practical It asks too much of human nature and opens the door to irregular practices and unhappiness

2 *Restriction of Intercourse to the " Safe Period "*—There is no period that is absolutely safe, but it is generally agreed that the likelihood of conception is least in the latter part of the intermenstrual period This is the best method to be adopted when birth control is desirable but not an absolute necessity It is the least objectionable

3 *Prevention of Entry of Spermatozoa into the Vagina* —One method is by coitus interruptus Generally speaking, this is unfair on the woman, as it is apt to leave her with desire excited but not satisfied It is not to be recommended The other method is the use of the condom When birth control is essential, but for a time only and the possibility of conception at a later date is to be preserved, the condom plan is the best It has been maintained that it is essential for the seminal fluid to come in contact with the vagina in order that the woman may reap the full benefit of the act , but this is not proved and I hold it to be doubtful

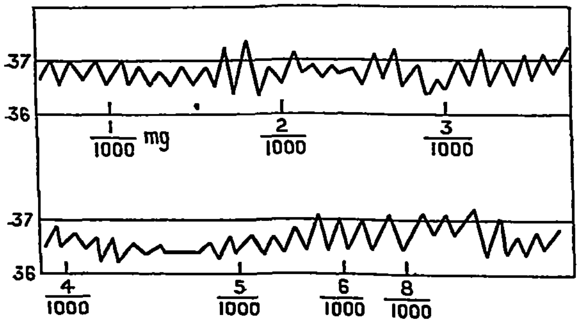
4 *Mechanical Prevention of Entry of Spermatozoa into the Uterus*—For this purpose various pessaries have been devised which are supposed to be introduced by the woman They are all uncertain in action, and their chief virtue is that they are a source of revenue to those who sell them

5 *Chemical Methods of Prevention of Entry of Spermatozoa* —The chief of these is the quinine pessary whose contents, when the pessary melts, kill the spermatozoa This is one of the most dependable methods, and it is free from the objectionable features common to some other plans It is to be recommended when birth control is to be permanent Douching is a method whose action is partly chemical and partly mechanical It is fairly safe, but not absolutely so ,

obtained improvement from these, tested in the various ways

The researches of Deycke and Much on *partial antigens, AFN*, are well known An enormous literature dealing with these remedies exists They have, however, not helped us as much as the old preparations of Koch I speak of several hundred patients who were treated with partial antigens, according to the method of Deycke and Much, and can say from my own experience that this troublesome method gave no better results than the other specifics Naturally we could raise the reactivity of the patient with the partial antigens, the results confirmed the value of allergic tests in prognosis The researches of Deycke and Much were especially valuable for the light thrown on the protective action of fats and lipoids, which, perhaps, has some meaning in regard to tuberculosis We know that the high lipoid value of the blood indicates a favourable, a low one an unfavourable, form of tuberculosis But it is questionable whether the defensive value of fats and lipoids is all that Much would have us believe

Recently we have been especially interested in *tebeprotin* of Tonniessen—a protein derived from tubercle bacilli, consisting of a chemically pure whitish powder entirely soluble in soda solution, and, therefore, permitting of accurate dosage This is an advantage over some other specifics It is less toxic than old tuberculin and causes a milder reaction The initial dose is 1/10,000 mg, or in strong subjects 1/1000 mg, given once a week in very slowly increasing doses up to 5/100 mg We have so far employed it in about 100 cases, and obtained as good results as with B E and S B E The proportion of patients who lost their tubercle bacilli under treatment was a little higher than our average We often had the impression that patients under this remedy who had subfebrile temperatures lost their fever more quickly, and that the foci showed a greater tendency to fibrosis than with other specifics With this remedy and the blood sedimentation test we can obtain useful information concerning the activity of the disease, testing the blood before and after an injection of 1/20–1/40 mg tebeprotin A definite retardation of sedimentation is a sign of active tuberculosis



A case treated with tebeprotin Shows feeble temperature reactions after the higher doses, finally reverting to normal, typical lymphocytosis and an increase in monocytes, the eosinophils remaining unchanged, Initial temperatures before injections max 37°, min 36 5° C Doses increased from 0 001 mg to 0 008 mg

So much for the subcutaneous use of specifics

Other Methods of Administration

Recently there have been attempts to utilise the important skin-resistance to infection By the introduction of stimulants subcutaneously, subepidermally or percutaneously one endeavours to set going processes which may usefully influence the focus and the general health of the patient In this way Klaus Schilling employed his "ertuban," a watery extract of human tubercle bacilli It is given at first in doses of 1/10,000 to 1/1000 mg, carefully increased Sahli has very thoroughly worked out his method of administering tuberculin subepidermally He made use of Beraneck's tuberculin, and began with the weakest concentrations, injecting 0 1 c cm Here, also, the doses are increased very slowly, always under the control of the allergic condition, the blood reaction, and the general health The percutaneous administration of specific stimulants may take the form of *liniments* (Petruschky), of Moro's ectebin, and other tuberculin *ointments* This method is appropriate, I think, in cases which are well suited for specific treatment, but in which the exudative character still predominates The method has been useful, more especially in children Still, we employ it in adults with low allergy, if temperatures become unstable, and the general course of the disease does not yet show a decided tendency to fibrosis of the lesions This percutaneous method of specific treatment is, as far as our experience goes, always milder in its effects than the subcutaneous, although even here there are unexpected exceptions Even these doses may cause mischievous local reactions, so that we begin with very small doses and long intervals

It has often been stated that the tuberculin liniments of Petruschky are not active, but our experience does not confirm this Certainly Moro's "ectebin" is more active, it is a mixture of dead tubercle bacilli in anhydrous lanolin Typical tuberculides result, furnishing immunising centres

In Germany Ponndorf's method is widely adopted This consists in scarification of the skin, followed by rubbing in of concentrated old tuberculin I must oppose this method unconditionally The activity is not controllable, the dosage altogether uncertain I have seen formidable local reactions and mischief to the patient from the method It may possibly be employed in the modified form of Gehrcke, Schmidt and Arneth, who recommend quite small patches and careful dosage, but I cannot find any advantage over the older methods

Yet a few words about the administration of these specifics *by mouth* Koch's preparations do not here concern us, as they are destroyed in the stomach and bowel, and we cannot follow the effect of the disintegration products in the lymph stream Deycke has recently warmly recommended his M T B R (Milchsaure - Tuberkel - Bacillen - Ruckstand) From blood examinations it has been shown that we have here to do with a definitely active therapy There was mostly a reversal of the serum albumin curve after these doses, and according to Meyer-Bisch there was a positive focal reaction (increase of water content of the tissue) We have confirmed these statements in patients and by animal experiments, and have also proved that general and local reactions may follow We would, therefore, urgently advise as great care to be exercised in this as in other methods of specific treatment

Protective Inoculations

We now come to protective inoculations against tuberculosis We have already explained exhaustively that we cannot immunise against tuberculosis with specific preparations According to present knowledge, we must admit that we can only be sure of immunising against infections by means of living virus The ideal would be to produce a focus which did not extend, in this way a certain protection would result This is what v Baumgarten and v Behring attempted in their inoculations of cattle Klimmer, v Ruck, Moller, and others have attempted the same in human subjects Moller and Friedmann worked with living bacilli from cold-blooded creatures Friedmann's method has, on the whole, as you may know, proved itself a failure There is, moreover, some danger of these bacilli becoming converted in warm-blooded subjects into pathogenic forms, from which I believe, they were originally derived Kolle, Schlossberger, Kaufmann and I have shown this in experiments on animals, though Calmette and other deny it (Photographs were shown from guinea-pig organs, showing a typical tuberculosis after the third transplantation with Friedmann's strain) Recently I had an opportunity to excise and examine endocrine organs The collateral zone of inflammation is a protective reaction. The reticulo-endothelial (mesenchymatous) tissues are stimulated When the stimuli are not too strong connective tissue results, which penetrates the tubercle and causes it to undergo fibrosis

Specific remedies are valuable because in suitable cases they can increase these natural reactions of the body when deficient

Allergy

We now come to the meaning of the so-called allergy We understand by this term an extreme sensitiveness of the whole cell-system of the infected organism to the infective agent and its products, as well as to some other irritants The Pirquet reaction is a good example of this allergy, which is a very useful guide to the degree of natural resistance The stronger the allergy, the greater the resistance Whether we can call forth a typical allergy with dead tubercle bacilli or tuberculin in a non-tuberculous body is not yet proven Observations, however, are increasing which prevent us from dismissing this possibility altogether

I need only remind you of the beautiful experiments of Bessau, who injected dead tubercle bacilli intraglandularly, and obtained thereby local sensitiveness to tuberculin which lasted for more than a year; of the experiments of his assistant, Fernbach, who reached the same end by intraperitoneal and intraglandular injections of dead virus; also similar results by the two Americans, Zinssew and Petroff I touch upon this subject here because it has a bearing upon our later consideration of protective antituberculous injections There was, however, always present tuberculous tissue in the above-mentioned experiments

Allergic behaviour and the degree of resistance to the infection run, therefore, to a certain extent, parallel We have seen this in thousands of cases, with increased allergic reaction there went not only improvement of the general health, but also of the local foci, whether the patients were treated with specific or non-specific or only general remedies, which (as already stated) also have a non-specific stimulating action Tuberculins are not immunising remedies Methods of treatment which aim at the reduction or abolition of sensitiveness to these preparations (so-called "positive anergy") are dangerous As a rule, in such cases all the allergic reactions return after a short time, but while they are feeble or absent we often see a decided tendency to metastases This was recently brought into prominence in Hamburger's clinic in the case of tuberculous meningitis of children We find in so-called "positive anergy" that tuberculous foci in the larynx, kidneys, bones, and joints do not heal up All these experiences and observations convince us that the end to aim at is the support and increase of allergy, not its artificial reduction

We need not here distinguish (with Much) between toxin sensitiveness and tuberculosis sensitiveness, this seems to me altogether hypothetical and not sufficiently confirmed experimentally Real anaphylatic reactions are not found in the tuberculous The tuberculin reaction is not to be regarded as an anaphylactic phenomenon

My view of the prognostic value of the allergic test, which the French medical school has long adopted, is finding more and more supporters There are many clinical and experimental observations which show that a strong allergy may be regarded as favourable, and which also prove that in many cases we can increase the reactive power of the infected organism by small doses of a specific stimulant In addition to the ordinary clinical tests of progress I make use of a graduated Pirquet, together with various blood-tests red corpuscle sedimentation tests, complement-deviation test, Arneth's blood count, proportion of lymphocytes, lipase, serum albumin These run parallel to a considerable extent.

Choice of Cases for Specific Treatment

Which cases are suitable for specific therapy, and how do we distinguish them? The clinical anatomical state of the patient is of very great importance in answering this question, since the cases tending to fibrosis are especially suitable. All those in which the exudative character of the disease is marked can only be treated specifically with the greatest caution. Before beginning such treatment the patients should always be kept for some time under careful clinical observation, using all the appropriate tests, although we cannot expect to divide our cases into purely fibrosing and purely exudative forms How could the clinician make such a diagnosis when the pathologist can only decide the anatomical nature of the cases with the help of the microscope? We have also to do with mixed forms in most cases we are called upon to treat Clinical experience, X ray pictures, a careful physical examination of the lungs, and, above all, prolonged clinical observations, can, however, determine the predominant character of a case, and this suffices for our purpose Moreover, the allergic behaviour is, in my opinion, most important in choosing our cases If there is a strong allergic reaction, if the blood count is normal, there is no fever, and the disease is mainly of the fibrosing type, then specific therapy is not necessary; general remedies will suffice. If, however, cases mainly fibrosing only give a feeble allergic reaction, if the blood count shows Arneth's movement to the left, if there is a small proportion of eosinophils and a reduction in the number of lymphocytes, if further there is a tendency to fever, if then we have the picture of a sinking resistance towards the disease, we are called upon to use specific remedies, and to try to raise the resistance. We should repeat the allergic and blood tests from time to time—blood counts, sedimentation, lipase, serum albumin When these show a notable improvement in resistance, we can leave off the specific treatment, if they again become less favourable, specific therapy is again indicated Absolute contraindications are long-standing fever, well-marked disturbances in the circulatory and nervous systems, strong tendency to metastasis, and, above all, a predominant tendency to exudation

A few words are called for concerning tuberculosis in children We all know that there is a well-marked tendency to recovery in the primary stage, so that these cases seldom come for clinical treatment The generalising forms in the secondary stage in children are mainly exudative; they often show a very strong tendency to resolution, and, as a rule, have a high degree of allergy I would strongly advise caution in attempting specific treatment in such cases, and recourse to prolonged general treatment instead

Choice of Remedy

What specific remedies should we employ? As you know, there are many tuberculin preparations from which to choose They differ in strength rather than in quality, and will all give similar results with appropriate dosage Formerly we used Koch's *Old Tuberculin* Many believe that with this remedy they get the best results, because it most easily and most certainly leads to so-called "positive anergy," or "biological cure" This view is untenable in our opinion, as already explained If we employ old tuberculin, we must use the smallest possible doses, beginning, perhaps, with 1/10,000 mg, rising very gradually to 1/100 mg, with intervals of eight to ten days Longer intervals should be left after each dose than is customary, to wait for the fall of the reaction Wright has done a notable service in showing the need of longer intervals between successive doses We can strongly recommend his method from our own experience. The dose is increased until the reactivity of the patient, tested in all the various ways already mentioned, has notably increased Then we should leave off specific therapy

As the old tuberculin seemed too toxic, we tried next the *B E* and the *S B E* We had good results also with these in hundreds of cases suitable for specific therapy We began with 5/1,000,000 mg and rose with intervals of 10 to 14 days to 1/1000 mg, Very seldom did we go beyond these doses, as we

† Case 16 received quinidine in October, 1922, and the fibrillation temporarily disappeared, but the abnormal rhythm returned in March 1923 and the patient became pregnant two months later

Parity.—P gr = Primigravida *Disease*.—M S & R = Mitral stenosis and regurgitation

Symptoms.—A F = Auricular fibrillation *Heart failure (pregnancy)*.—E. = Early P = Present

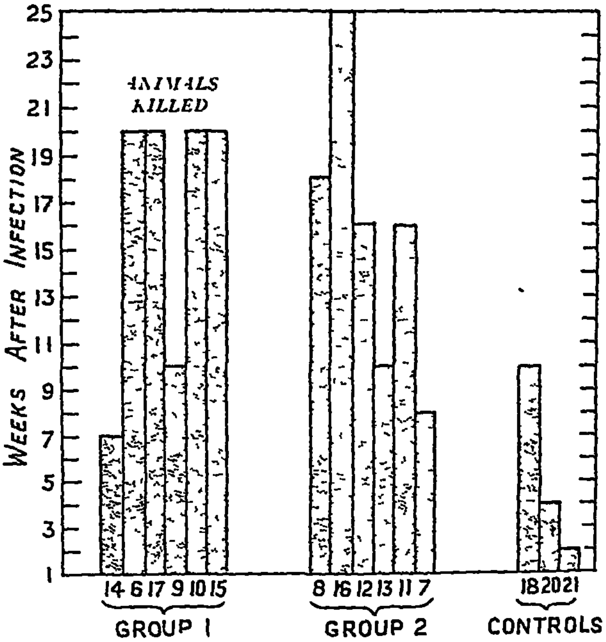
Duration of in patient treatment.—R D = Response to digitalis (*a*) Month later heart again broke down (*b*) In bed three months at home without response, intolerant to digitalis (*c*) Too ill to move to hospital (*d*) Not maintained in later months

Method of delivery.—N F = Natural forces

Heart failure (labour).—*Prolonged labour owing to difficult breech with extended legs

Immediate result.—(*e*) Abortion induced death 22 days after delivery (*f*) Died undelivered two days later (*g*) Died suddenly three days after admission before onset of labour (*h*) Left hospital fairly well, died suddenly three months later a fistula caused by Friedmann's method of treatment The section showed typical tubercles Such a focus naturally has an immunising effect, but is not without its dangers

During the last few years attempts have been made to immunise animals and children against a virulent tuberculous infection, by means of more or less weakened and non-pathogenic virus I refer to Selters's vital tuberculin, Calmette's B C G, strains grown by Arima, Aoyama, and Ohnawa on culture materials containing saponin, to Raw's preparation, in which tubercle bacilli killed by heat are employed, to Shiga's and Langer's vaccines In all these vaccines we have to do with more or less non-virulent bacilli We cannot yet give a final verdict upon these methods There are very serious objections to them, and in any case years must pass before we can be sure of their value



Survival of infected rabbits with and without protective inoculations

Recently I made similar experiments in connexion with my investigations on the influence of splenic extracts on tuberculously infected animals With the help of extracts from lymphocytic organs we can biologically produce vaccines containing entirely non-virulent tubercle bacilli With these vaccines I tried to protect rabbits against subsequent bovine infection Protection followed for some months, and where infection eventually resulted there was a noticeable increase in resistance The above diagram illustrates the duration of life in three groups of rabbits experimented upon The first group consists of animals inoculated and then infected Four were killed, and found to be free from tuberculosis The second group consists of animals inoculated after infection These died of tuberculosis, but survived considerably longer than the controls, and on examination showed a greater tendency to fibrosis The third group (controls) consists of animals infected without any protective inoculation In these was found a tuberculosis spread over the whole of the lungs This was not found in any animal which had had a protective inoculation

These vaccines evidently give a notable protection against following infection. Whether they are capable of starting healing processes in human tuberculosis remains to be proved In a few patients there seemed to be a beneficial influence I cannot say more, as there has been too short a time for observation Still, these experiments point out a way in which active immunisation against tuberculosis may be obtained.

Passive immunisation by means of serum I do not believe to be possible, in spite of the numerous attempts that have been made. All the sera hitherto recommended by Marmorek, Maragliano, Ruppel, Uhlenhuth, and others have led to no practical results

Serum therapy is, in my opinion, in tuberculosis a non-specific stimulant therapy If we wish to employ such non-specific remedies, we can do so more safely with Lipatren from the Behring works

Ambulant Therapy

If we review all the facts concerning specific therapy, it is obviously by no means easy, and needs such a careful observation of indications and so exact a clinical control that it cannot be carried out under ambulant conditions without the greatest difficulty We have always taken the view that ambulant specific treatment is to be avoided We believe, however, that it can be carried out under ambulant conditions if it was previously employed with benefit in a sanatorium or hospital where all the necessary details have been observed In that case the practitioner who is possessed of all the data can continue the treatment with success He must, however, continue to observe all the clinical details and record them, together with the general remedies employed

It is not possible to state the results of specific treatment statistically. The recoveries which I have seen are about the same statistically as those obtained with gold salts alone, or exclusively with general remedies The value of specific therapy can only be estimated in each case separately, and in this way we come across patients who obviously profited by specific therapy in addition to our other remedial measures

THE EFFECT OF PARTURITION ON THE HEART

WITH A REPORT ON EIGHTEEN CASES OF PREGNANCY COMPLICATED WITH AURICULAR FIBRILLATION

BY A. LEYLAND ROBINSON, M D LOND,
F R C S ENG,
HON SURGEON, HOSPITAL FOR WOMEN, LIVERPOOL

THE normal heart is composed of healthy muscle, has competent valves, and maintains a regular rhythm, and possesses a reserve power which ensures a smooth physiological response to extra, and even extraordinary, effort The effect of diseased processes, whether they be muscular, valvular, or rhythmic, is to reduce the efficiency of the heart by limiting the capacity of this reserve force If the disease is progressive, or the demand for work excessive, then sooner or later the reserve force is so reduced that the heart is unable to meet the demands made upon it.

A pregnant woman with auricular fibrillation has her cardiac reserve power depleted by the following factors or loads (1) the valvular lesion, (2) the altered rhythm, (3) the strain of pregnancy and labour, and apart from this mechanical factor, the frequency of toxæmic states must not be forgotten—conditions in which degenerative changes are commonly found in the musculature and blood-vessels

The association of pregnancy and fibrillation forms a complex that embraces all the commonest and most powerful factors concerned in the production of heart failure The mechanism whereby heart failure is produced by these loads belongs to the province of the cardiologist, but the influence of pregnancy and labour is of peculiar interest and importance to the obstetrician, and requires some amplification

Effect of Parturition on the Normal Heart

Pregnancy—The weight of the child is a mechanical stress that increases as pregnancy advances The growing uterus displaces the abdominal organs, compresses the diaphragm, and impedes the movements labour produce the maximum muscular strain, and that subsequent labours are frequently short and easy, yet repeated pregnancies should be forbidden to all patients who have any heart lesion There are many reasons for this view, but three only need be mentioned here (1) muscular atony and degeneration are the common sequelæ of repeated pregnancy and lactation, even in healthy women, (2) many cardiac lesions are progressive processes—e g, mitral stenosis, (3) recurrent endocarditis may be set up by the pregnant state

This question is one that must be referred to the cardiologist, who may consider that the cardiac efficiency is so little impaired in any individual case that more than one pregnancy may be permitted to the patient In any event, adequate spacing of the children is essential in order that the heart may be given ample time to recover from the strain of one pregnancy before being exposed to the effects of another

(*d*) *Mode of Delivery*—If the cardiac reserve is sufficient to enable the patient to play games and lead an active life when not pregnant—i e, almost perfect—normal delivery at full term may be safely allowed, at the same time, the induction of premature labour and the use of forceps are always useful procedures, as they mean less work for the expelling muscles and, consequently, less strain on the heart For cases in which the cardiac reserve is seriously reduced Cæsarean section is probably the least risky mode of delivery This operation has many advantages

1 The strain entailed by the anæsthetic is no greater (sometimes less) than the cardiac work demanded by the uterine contractions and the voluntary efforts of the accessory muscles, even when assisted by forceps traction

2 It is the most rapid method

3 It can be carried out deliberately at a chosen moment and under the most favourable conditions

4 The amount of blood lost can be regulated and the puerperal plethora prevented

5 It offers a certain method of sterilisation by excision of a portion of both Fallopian tubes, which conserves the regular menstrual loss (clearly an advantage to the cardiac subject)—a method which compares most favourably with the uncertainty of contraceptives and the disadvantages of the amenorrhœa induced by X rays

Cæsarean section is specially indicated when the patient is a primipara or where there is some additional obstetrical complication, such as a contracted pelvis or an abnormal presentation I have had personal experience of five operations for severe heart disease with good immediate recoveries, and am convinced that this method of delivery is the method of choice for many cases

Conclusions.

The results tabulated in this paper show that heart failure is a dangerous complication in parturition and suggest that the rational basis for the treatment of heart disease and pregnancy depends upon three important facts 1 Pregnancy and labour absorb the reserve power of the heart, and the amount of reserve force required increases as term approaches 2 A woman with organic heart disease who becomes pregnant starts with a depleted cardiac reserve, which may or may not be sufficient for the inevitably increasing demands of the pregnant state 3 Labour in the presence of severe heart failure is either immediately fatal, or greatly hastens the fatal termination of the case

The principles of treatment may be summarised as follows 1 A woman with serious depletion of the cardiac reserve should not become pregnant 2 If conception occurs in the presence of seriously depleted reserve the pregnancy ought to be terminated before the onset of heart failure 3 The induction of labour in the presence of heart failure is unjustifiable 4 Artificial termination of the pregnancy should be carried out when cardiac compensation has been re-established—and for many cases Cæsarean section is the best method of delivery

---

DEATHS UNDER ANÆSTHETICS.

BY A GOODMAN LEVY, M D, M R C P. LOND,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS

THE reports of the Registrar-General on deaths under anæsthetics for the last few years contain statistics and remarks of considerable interest and deserve careful study The following table is adapted from these reports, the statistics contained in it date from 1911, because a modified system of registration came into operation on that year —

England and Wales Deaths Under or Connected with the Administration of Anæsthetics

In some of the death certificates the nature of the anæsthetic is not stated The statistics are therefore grouped as "stated" and "unstated"

Year	Number of deaths						Anæsthetic stated, per cent of total	Per cent of total stated			
	Total	Nature of anæsthetic		Chloroform		No chloroform		Chloroform (alone)	Chloroform in combination	Ether *	Other anæsthetics
		Stated	Unstated	Alone	In combination						
1911	276	214	62	142	46	26	78	66	22	9	3
1912	283	181	102	117	31	33	64	65	17	13	5
1913	296	185	111	110	33	42	63	59	18	14	9
1914	300	193	107	110	36	47	64	57	19	18	6
1915	261	171	90	102	39	30	66	60	23	15	2
1916	306	200	106	112	52	36	65	56	26	14	4
1917	280	196	84	106	59	31	70	54	30	11	5
1918	279	188	91	81	61	46	67	43	32	18	7
1919	302	232	70	96	74	62	77	41	32	21	6
1920	366	282	84	96	95	91	77	34	34	26	6
1921	337	264	73	82	87	95	78	31	33	27	9
1922	336	260	76	63	93	104	77	24	36	30	10
1923	446	392	54	87	148	157	88	22	37	32	9

* Including "ethanasol" and "gas and ether"

Increase in Total Number of Deaths

The yearly number of these deaths increased suddenly in 1920 to 366, and this increase has been sustained In 1923 there was a great increase to 446[1] In explanation of this increase the report for 1923 suggests that there may be included in recent years an increasing number of deaths not actually connected with the anæsthetics, because the certification of deaths is steadily becoming more detailed I rather doubt if this slowly acting cause could account for the sudden rises noted, and further there exists a well-recognised and growing tendency to omit the mention of the administration of an anæsthetic in death certificates whenever possible I do not think that this argument can be admitted in relation to the registration of anæsthetics

We do, however, have to take into consideration the yearly increase in the number of operations during the period under consideration This increase is computed at 13 per cent from the theatre statistics of a large general hospital in London It must also be noted that deaths from delayed anæsthetic poisoning and acidosis are first returned as such in the year 1919, possibly, but not certainly, these help to swell the total These cases would not account for more than a 5 per cent increase at a liberal computation

The foregoing considerations barely account for the 22 per cent rise in the number of deaths in the period 1911–22, and are totally inadequate to account for the 62 per cent rise in 1923 I think, therefore, we must conclude that up to the present moment little or nothing has been effected in the progress of years, either through the medium of new knowledge or new methods, in the way of reducing the general liability to death under anæsthetics

Chloroform—In the earliest years of this century deaths under chloroform constituted over 80 per cent of the lower lobes of the lungs; and although the subcostal angle is opened out, the lower ribs expanded, and the apical respiratory excursion shows enhanced movement as compensatory phenomena, yet, in spite of these adjustments, the expansion of the lungs is diminished This applies to all pregnant women in some degree in the second half of pregnancy, but especially to primiparæ and to pregnancies complicated by hydramnios and twins, where the physiological tumour is unduly big The effect of this pressure is shown by shortness of breath on exertion, and is demonstrated by the presence of crepitations at the pulmonary bases, which disappear in healthy women after a few deep breaths have been taken The heart itself is dislocated upwards by the uterine tumour, which presses chiefly on the right ventricle

---

[1] The report for 1924 has now been published The total number of deaths in that year was 429

The circulatory changes include a definite blood plethora, which is a physiological response to the increasing demands of the rapidly growing maternal and fœtal tissues New vessels comprising the placental circulation increase the work of the heart by interposing an additional vascular field, whilst the pressure effects described above further increase the peripheral resistance by obstructing the venous return The normal heart meets these demands by calling upon its reserve force, and the patient may be unaware of any limitation of cardiac efficiency—but some encroachment on reserve is always made, and the amount increases throughout pregnancy

Labour—The effects of labour are simply those of muscular effort which always imposes a strain on the heart and calls on the cardiac reserve The strain is slight in easy normal deliveries, but may be very severe when labour is prolonged or delivery difficult

Puerperium—In all cases the contractions of the puerperal uterus empty and occlude the vessels of the placental site, and thereby inject an additional amount of blood into the maternal circulation, unless post-partum hæmorrhage occurs or the patient is deliberately bled (to prevent plethora)

Effect on the Abnormal Heart

If the demands of normal pregnancy and labour inevitably call upon the reserve power of the heart, it is clear that the chief issue in any case of pregnancy with heart disease must depend upon the amount of reserve force left in the damaged organ If this is considerable, then the strain of parturition may be easily overcome, if it is small, the outlook is serious, whilst the combination of pregnancy with actual heart failure—i e, complete absence of reserve force—is always highly dangerous That such is the case is strongly supported by the fact that out of 18 patients with auricular fibrillation in pregnancy whom I have observed, 13 died either before, during, or soon after delivery. All of these patients were suffering from heart failure and mitral stenosis, with an added aortic lesion in three cases It should be noticed that the liaison of mitral stenosis and pregnancy is peculiarly apt to set up heart failure, because obstruction in the pulmonary circuit is produced by the valvular defect and also by the selective pressure effects of the pregnant uterus It is, therefore, not surprising to find that the association of these two factors greatly enhances the action of each and exerts the most unfavourable and damaging pressure on the right side of the heart

The accompanying table gives an analysis of the salient features of these 18 patients so arranged as to show the natural history of fibrillation during pregnancy, labour, and the puerperium, with the treatment, the method of delivery, and result of each case It brings forward ample clinical proof of the truly malignant influence of parturition on the failing heart, and shows that the conduct of such cases requires the most careful consideration of both cardiologist and obstetrician

The immediate treatment of the fibrillating or failing heart by rest and drugs of the digitalis group is well known and easily carried out, but the cardiologist has a much more difficult task to perform. The immediate response may be good, but it does not necessarily throw any light on the ultimate result, which depends essentially on the quality of the heart muscle and the amount of reserve power left in the damaged organ The cardiologist alone can determine—perhaps it would be more accurate to say estimate—this unknown quantity, indeed, only the physician who has special facilities for the study of the effect of pregnancy and labour on heart disease can realise the difficulty of prognosis and be really helpful to the obstetrician who is faced with the grave responsibility of the delivery of the patient Too much emphasis cannot be laid on the fact that the injurious effects of pregnancy are progressive and cumulative—insignificant, perhaps, in the early months or so long as the cardiac reserve holds out, but increasing, often rapidly, as term approaches and culminating in the supreme strain of labour The cardiologist is thus confronted with a double problem he must first estimate what is left of the cardiac reserve after allowing for the loads imposed by the valvular lesion and the rhythmic and other pathological changes that may be present, and he must then decide whether the progressive and cumulative demands of labour and the puerperium will, or will not, absorb all that is left of this reserve The results published in the present paper demonstrate that a heart without reserve power is unable successfully to withstand the strain of parturition, and that the conduct and prognosis of all cases of heart disease and pregnancy are vitally dependant upon the presence or absence of heart failure

Treatment of Heart Disease and Pregnancy

(*a*) *Without Heart Failure*—After full investigation of the heart and full allowance for the various cardiac loads, the pregnancy may be permitted to continue so long as the cardiologist estimates the reserve as satisfactory and the patient consents to remain under observation and supervision If, at any time, the heart begins to show signs of diminishing and defective reserve, the pregnancy must be terminated before actual heart failure has supervened.

(*b*) *With Heart Failure*—Unfortunately, a patient may become pregnant when her heart is imperfectly compensated, or she may develop heart failure before seeking advice, or even when under treatment Under these circumstances the obstetrician is often advised to terminate the pregnancy forthwith This, however, in my opinion is dangerous advice, because the combination of labour and heart failure is incompatible with the safety of the patient, and there can be no valid reason for submitting an already overburdened heart to an additional strain The spontaneous onset of labour may be unavoidable, but the deliberate induction of labour is certainly unjustifiable when heart failure is present The same principle applies to the early months of pregnancy, although the application is somewhat different, heart failure at this stage cannot be primarily due to the changes produced by conception because the circulatory and pressure effects are insignificant until the fifth or sixth months of gestation Heart failure in early pregnancy is, therefore, very much less the result of the pregnancy itself than of other intrinsic causal factors, and although the uterus may possibly be emptied without disaster, this proceeding is not likely to have any immediately favourable effect on the failing heart, and is not worth the risk it undoubtedly entails

On the contrary, every effort must be made to restore the compensation of the heart before the termination of the pregnancy is decided upon, but in view of the inevitability of the spontaneous onset of labour sooner or later, the importance of delivering the patient at the first favourable opportunity needs emphasising In severe cases this moment has arrived when the patient is reported by the cardiologist to be in a condition to withstand the strain of Cæsarean section

(*c*) *Control of Repeated Pregnancies*—Although it may be fairly advanced that the first pregnancy and functionless. Treatment has consisted in the exhibition of iodine in many forms, in massage, and exercises. The head at present can be bent laterally about 5 degrees and turned similarly. All the spine can be moved very slightly indeed, even with great and prolonged exertion on the part of the patient but the knees can be flexed to 90 degrees—i.e., the patient can kneel. The temperature, pulse, and respiration have throughout remained normal.

Spondylitis deformans and its varieties have several synonyms—spondylose rhizomelique, von Bechterew's disease and Marie-Strümpell's disease. It can be divided[1] into two main types, (*a*) diffuse osteo-arthritis of the spine, and (*b*) diffuse ankylosing arthropathy. The former is a comparatively slight disease, but the latter more serious. It occurs between the ages of 20 and 40 years and affects the intervertebral discs thus producing ankylosis. New bone formation often occurs in the anterior common ligament. In Marie-Strümpell's disease the lumbar spine is first affected and in von Bechterew's[2] the cervical, whilst in the spondylose rhizomelique of Marie the spine is affected with the hip- and shoulder-joints. In any group, if ankylosis precedes the destruction of the discs, "poker-back" is produced, but where the reverse is the case the "aged-rustic-back." In the 120 cases discussed by McCrae[3] 60 involved the spine alone and 60 the peripheral joints also. 80 per cent of the cases were in males. Jones and Lovett[4] discuss the importance of gonorrhœa in the ætiology.

The first case of *myositis ossificans* was described by Guy Patin in 1692 and the second by Freke in 1740.[5] The disease is subdivided into two distinct groups, (*a*) traumatica with local changes due to the tearing away of osteogenetic tissue and (*b*) progressiva. This is frequently described as congenital, and Burton-Fanning has reported an hereditary case.[6] Of Lorenz's 45 cases 38 occurred before the fifteenth year and 11 in the first year of life.

The sex incidence shows that males are affected four or five times more frequently than females, and the race incidence that the great majority of cases occur among the Anglo-Germanic peoples. Munchmeyer first described the pathology in 1869, but concerning this there appears to be no general agreement at the present time, some authorities regarding the condition as a neoplastic occurrence, others as an embryonic aberration, and others as due to chronic inflammation. They are agreed, however, that in all, or almost all, of the general cases microdactylia occurs in the hands or feet, especially the big toes, "due to suppression of the proximal phalanx or stunted first and second phalanges." Less often there is a similar malformation of the thumbs.[8] In 1918 Rosenstirn collected and analysed all the published cases, 120 in all.[9] In only one case can it be proved that microdactylia was absent.[10] Burgerhout carried out extensive researches into the metabolism of patients with the disease, but could find no definite abnormality.[11] In his conclusions Rosenstirn suggests the renaming of the general disease as fibro-cellulitis ossificans progressiva, as it is in the fibrous tissue that the earliest changes occur. He is satisfied that in M. ossificans traumatica the ossification first takes place in the connective tissue surrounding the extravasated blood, that there is no diminution in the Ca excretion nor other evidence of Ca retention. In the case now reported it is not considered clear to which group the patient belongs.

I am indebted to Dr. J. Murray Bligh, senior physician of the David Lewis Northern Hospital, Liverpool, for permission to publish these notes and to Dr. W. Oram for his assistance with the radiography.

of the total number The fall to 22 per cent has no doubt been largely conditioned by the substitution of chloroform and ether mixtures, and sequences of these, for pure chloroform, the tendency in later years being to avoid the use of pure chloroform The possibility is not excluded that the mortality-rate from the use of pure chloroform may be diminishing, but on this point there is no definite evidence available

Chloroform in Combination —Before 1911 the average percentage of deaths under this heading was 7 per cent The rise is evidently correlated with the increased employment of chloroform in mixtures, and Hewitt and Blomfield's[2] paper, published in 1909, stands out as a boundary mark in this connexion At the present time chloroform in combination accounts for more deaths than any other form of anæsthetic

An analysis of the deaths under this heading may be of interest In 1923 out of 144 deaths recorded of this nature, nine occurred under a chloroform to ether sequence 11 under a C E or A C E mixture to ether sequence, and the remaining 124 under C E mixtures of varying proportions There were none recorded under an ether to chloroform sequence Up to 1917 the combined " chloroform " and " chloroform in combination " percentages remained fairly constant, the average being 83 per cent of the total, but thereafter these combined percentages gradually fell away to 59 per cent It might, therefore be considered that combinations and sequences are now tending in some measure to increased safety I do not think that this would be a correct interpretation, the deficiency balance is transferred mainly to the heading " deaths under ether," and the following considerations bear upon this point

Ether —In 1911 the percentage of deaths under ether was 9 per cent, and the average for previous years was somewhat lower. In 1923 it had risen to 32 per cent In my student days, about 1890, ether administered by means of the Clover's inhaler was regarded as a practically safe anæsthetic; the few deaths that occurred under its influence were mainly the result of regurgitation of fluid in intestinal obstruction or of other unavoidable accidents With the advent of the extended employment of the " open ether " methods it has become, according to these statistics, an agent of remarkable lethal potentiality In 1923 no less than 123 deaths were recorded from the use of pure ether How can we account for this ?

I have examined the records of these 123 cases, they were cases such as would occur in the ordinary routine of hospital operations, many being trivial, it follows that an undue proportion of very serious operations was not a conditioning factor That there have been incidents of sudden cardiac syncope under the administration of pure ether can hardly be doubted, their explanation is obscure, and their recorded occurrence has been exceedingly rare It is not possible to believe that such incidents can have multiplied to an alarming degree in recent years

There appears to me to be only one acceptable interpretation of the rise in the number of deaths under ether, and that is that the death certificates have been incompletely filled in Owing to a certain element of delay in the induction of anæsthesia by ether when administered by the " open " method, it is a very general practice to commence the induction with chloroform or C E mixture and then to change to pure ether, such a routine administration is liable to be returned as one of " open ether " or " ether," and no mention made of the preceding, and possibly brief, administration of chloroform

In 1923 there were only 20 deaths recorded under a chloroform or C E to ether sequence, and 123 under pure ether Having regard to the prevalence of the sequence method, these figures lend strong support to the theory that the returns are erroneously rendered There can be little doubt that a large proportion of these " ether " deaths should be transferred to the category of deaths under " chloroform in combination "

Conclusion

It is, I believe, commonly considered that chloroform is rendered " safe " by diluting it with ether, and that a small amount of chloroform at the commencement of an administration of ether is of no consideration In both of these circumstances chloroform tends to become, in my view, unsafe for general routine purposes At least the reports of the Registrar-General serve to dispel the idea that chloroform is safe when employed under such conditions The pros and cons of this matter might, I am aware, be discussed at considerable length, but I think it better to leave the foregoing record of facts and brief comments to the consideration of those interested

I have to express my thanks to the Registrar-General for access to statistical material in his office

A CASE OF
SPONDYLITIS DEFORMANS WITH MYOSITIS OSSIFICANS

By C W HEALEY, *M C*, M D LIVERP,
HOUSE PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

THE interest in this case appears to be (1) the difficulty of diagnosis in the earlier stages, (2) the extreme rarity of the concomitance of two in themselves rare diseases, and (3) the perfect symmetry of the ossifacient changes

A B, a seaman aged 27 years, was first seen by Dr J Murray Bligh on Oct 26th, 1920, suffering from pain and stiffness in the back of the neck, and pain on pressure over the ribs His mother was English and his father Italian by birth, although his (the father's) father was a Jugo-Slav who had married an Italian wife There was no history of any family abnormality of any kind or of dystocia when the patient was born He could recall no accident or undue strain prior to the onset of symptoms, but gave a history of " rheumatic pains " flitting from joint to joint in 1918 and 1919 He was much exposed to the weather at sea the following winter (1919–20), when he found it painful to move the cervical spine and to jump from one level to another, as this caused jarring in the occipital region The pain was dispelled by aspirin and any liniment At that time an X ray examination of the neck proved negative Six months before the first examination, that is, in May, 1920, he had contracted gonorrhœa in France, so that the provisional diagnosis of gonococcal arthritis was made. The patient had great pain in the left temporal, occipital, and clavicular regions in 1921 The gonorrhœa was treated in America, and urethral smears were negative in 1922 (Liverpool and Philadelphia)

Condition on Admission —On July 24th, 1925, the patient was admitted to hospital after getting gradually worse His head was held facing half-right, there was complete " poker-back," and an inability to sit down Crutches had to be used for locomotion and standing, and in order to lie on a bed from the standing position the patient had purposely to overbalance The shoulders, elbows, wrists, and hand-joints were normal, but the hips were immobilised and the knees could not be flexed more than 60 degrees from the straight position The ankle- and foot-joints were normal The chest expansion was only from 30¾ in to 31¼ in The blood pressure was 145/120, and the Wassermann reaction was negative Radiograms taken about this time show apparent fusion of the articular processes in the cervical and other regions of the spine with some ossification in the cervical portion of the anterior common ligament, an absence of bone changes at the shoulder-joints (the hip-joints cannot be clearly seen), and perfectly symmetrical myositis ossificans of the glutei maximi (well shown on the accompanying radiogram). No other groups of muscles were similarly affected, and the hands and feet were normal Urethral smears were negative for gonococci, an injection of 2½ millions gonococci produced neither local nor general reaction, and the gonorrhœal test was negative

The blood calcium was only 9 3 mg per 100 c cm It was considered inadvisable to excise the ossified parts in view of the important structures in the gluteal regions, and the possibility that from long fixation the hip-joints were marked in all cases suffering from dehydration The clinical picture was that of an acute dyspepsia in the majority of cases

[2] A Report on the Routine Use of the Open Method of a Mixture of Chloroform and Ether By F W Hewitt and J Blomfield, THE LANCET, 1909, ii, 10

Temperature—Some cases had no fever, whilst in others the temperature varied from 100° to 102° F, and sometimes it rose to 104°

Stools—These were usually green, offensive, and very watery, in a few cases small spots of blood were seen mixed with mucus The number of stools varied between four and ten a day The skin remained elastic in all the cases that I saw There were no cases with symptoms of acidosis The stage of intoxication was reached on the third or fourth day in the few instances where I was asked to see the patient Fortunately they did not prove fatal In these cases the commencement of treatment had been delayed

Treatment

Two or three meetings were held at which I explained the plan of treatment to the health visitors, district nurses, and superintendents of infant welfare centres, also the superintendent of St Mary Abbot's Hospital, Dr Remington Hobbs The method of treatment is very similar in outline to the one suggested by Dr Donald Paterson in a lecture he gave in 1923 It consists in absolute starvation for at least 24 hours, and, when the vomiting had subsided, normal saline half the usual strength—namely, half a teaspoonful of salt to the pint of water—was to be given to the child in bottlesful cold, and the child allowed to drink as much as he wanted Some children took over two pints a day One teaspoonful of castor oil was to be given when the vomiting had subsided, and this was the only drug administered At the same time the intestine was to be washed out with saline, and this was to be continued once a day while the diarrhœa lasted The next day the child must be given food which it can digest In this condition any food having a high protein and a low fat content is suitable, such as skimmed dry milk, protein milk, or malted milk. On the whole I found that malted milk was better tolerated than skimmed milk during the acute stage, so I advised the nurses to take a bottle of malted milk next day and to tell the mothers to give two teaspoonfuls of malted milk in 2 oz of water every three hours in cases where the infant was under 3 months, when over 3 months 3 oz of the food was to be given, and in cases where this amount was tolerated and the child not satisfied the quantity could be increased a teaspoonful a day more of the malted milk with an ounce of water There were very few instances where the food was vomited Three teaspoonfuls of malted milk contain about 45 calories, so that an infant would receive, if fed three-hourly, 270 calories per diem Windows and doors were to be kept open during the hot weather Light clothing only to be put on the child Tepid sponging was not advised because it would cause unnecessary movement

Results of Treatment

I got the best results when malted milk was given for at least five days or until symptoms of acute dyspepsia had subsided On no account should the food-supply be diminished, provided there is no vomiting, even in cases where the diarrhœa continues I would even go so far as to say that the diarrhœa by itself was of little account provided the child was improving and taking its food well and having plenty of water between the feeds In most cases the diarrhœa gradually subsided and the motions became less offensive, provided a rectal wash-out was done daily The effect of the saline by the mouth in reducing the shock and collapse was surprising The eyes became less sunken, and the abdomen returned to its normal shape in about two days If the diarrhœa continued after about ten days I gave some bismuth No opium or alcohol was used Cases of high temperature did well on this treatment No drugs were given to reduce it

Feeding

The return to normal feeding was the real difficulty It is impossible to give a detailed description of the various methods employed in individual cases, but I was greatly struck by the desire of the mothers themselves to carry out the instruction which they received Any plan for adoption in the home must be of the simplest description, or else it is sure to fail.

I gave instructions that in all cases where the child was doing well, and had been on malted milk for a week, ten drops of cow's milk should be added to the malted milk in each feed, if no symptoms of indigestion occurred, the next day 20 drops were to be given, and the day after one teaspoonful in each feed If all went well up to this point a teaspoonful more of cow's milk was added every day until as much as 1 oz of cow's milk was given At this stage the malted milk was reduced one teaspoonful at a time for every ounce of milk added Eventually we got to a diluted milk mixture with half a teaspoonful of sugar, and, lastly, cod-liver oil in one drop doses and the effect carefully watched, if it caused vomiting it has to be omitted for a few days and then tried again, the amount of cod-liver oil never to exceed three drops in each feed The difficulty in digesting fat is peculiar to these cases This régime can be carried out by the mother with the nurse's supervision In cases of difficulty I was asked to see the patient

It is interesting to note that even in the case of breast-fed infants it is necessary, after 24 hours' starvation and salt water, to give malted milk during the first three days The mother during this period must be encouraged to massage her breast so as to keep the secretion active After the three days, or when acute symptoms have subsided, the child can again be fed on breast milk We had difficulty in some cases to persuade the mothers to resume breast-feeding Some children could not digest ordinary cow's milk, but did well on dry milk mixtures The malted milk was supplied free by the council as a temporary measure under medical supervision

Prognosis

What influences the prognosis more than anything is the time that elapses between the onset of symptoms and the commencement of treatment If the treatment is delayed beyond 24 hours the prognosis is far more serious, not only as regards the life of the child, but also the amount of injury done to the digestive system

Inspection after Treatment

I visited the cases who had received treatment, after the summer was over in each year, and the majority were doing well A few had been admitted to hospitals, and these were usually the under-weight infants Some had done much better since the attack, with the resulting supervision of their diet.

I am indebted to Dr Fenton for the following figures The number of deaths in infants under the age of 1 year attributable to zymotic enteritis in the borough during the last five years —

1921	77 deaths	1924 .	18 deaths
1922	22 ,,	1925	22 ,,
1923	42 ,,		

Number of notifications of zymotic enteritis since July 1st, 1924, were 245 In 1924 there were 40 In 1925 there were 122 In 1926, 83 The death-rate in 1926 up to Sept 30th, amongst 83 notified cases of zymotic enteritis was only six The death-rate in 1926 from all causes of enteritis was 28 up to Sept 30th

During the last three years the number of cases attended by the District Nursing Association of Kensington was 187 Among these 187 cases there were only two deaths I only sent one case into hospital during the three years The last time the disease showed itself in epidemic form was 1921 Since then there have been no epidemics, but it is encouraging to see that the death-rate from zymotic enteritis has been so appreciably diminished during the last year The last two summers have certainly been warmer than 1924, so that I think the scheme has been tested The educational influence of the council's scheme is beginning to have a marked effect on the population of North Kensington, because they see the excellent results of early treatment, and they

THE PREVENTIVE TREATMENT OF SUMMER DIARRHŒA

ROUTINE MEASURES IN THE HOME

BY RONALD CARTER, M D BRUX , M R C S ENG ,
PHYSICIAN FOR PEDIATRICS AT ST MARY ABBOT'S HOSPITAL (MUNICIPAL HOSPITAL OF KENSINGTON), PHYSICIAN, INFANT WELFARE CENTRE, KENSINGTON

MY object in bringing this subject before the notice of the profession during the winter months is to allow time for the proper organisation of preventive measures before the hot weather commences. It is essential for the success of the treatment that an adequate scheme should be in existence at any rate before June.

The infant welfare movement has, no doubt, done a great work in educating the public and also the medical profession in the proper feeding and general hygiene of infancy and early childhood, but much remains to be done amongst those who do not avail themselves of the advice which can be obtained at these centres. Gastro-enteritis, zymotic enteritis, or whatever name we like to give the condition, still claims too high a death-rate between June and September during the first two years of life. The disease chiefly affects children living in large towns. Amongst those who recover we must not forget the "injury-rate" that occurs in many instances and which interferes with growth and nutrition for many months afterwards.

The hospital authorities are all agreed that the cases are sent to them too late and that treatment should be begun much earlier. The bacteriologist has failed to isolate any specific micro-organism after many years' patient search. He tells us that there is an enormous increase of organism that normally inhabit the bowel, and that the child dies of an infection from the bowel. The pathologist can usually find nothing noteworthy except fatty degeneration of the liver, the intestines which have been subjected to very severe treatment usually show no marked signs of disease.

The clinician, therefore, must depend on himself entirely, he cannot expect any practical suggestions from the laboratory expert. The clinician must, therefore, concentrate on the child rather than on the disease, he must devise some method by which the body can quickly recover itself from the first onslaught of the enemy, and then give some form of nourishment which should be the least irritating and that should, at the same time, contain sufficient nourishment to satisfy the caloric requirements of the child after recovering from the initial shock. This is, roughly, the problem before us. It was felt in Kensington that something more should be done to diminish the number of moribund cases which were being sent to the hospital, and also to lessen the injury to the digestive system after the acute symptoms had subsided. I was asked to devise a scheme for treatment in the home which could be easily carried out and which would be helpful to the general practitioner in the neighbourhood.

Ætiology

The literature on this subject is vast, and anyone wishing to become acquainted with it could not do better than consult the bibliography at the end of Dr Donald Paterson and Dr D Nabarro's paper on epidemic diarrhœa which appeared in THE LANCET of 1922, ii, 325. The theories of Czerny and Finkelstein at one time occupied a prominent place in the causation of infective diarrhœa. They thought that the chemical action of food and its decomposition products were a sufficient cause for summer diarrhœa, rather than the action of bacteria. Theories based on the chemical action of food products have given place to the infective theory again, and in 1920 Dr Bloch, of Copenhagen, pointed out that the clinical picture, pathological findings, and the epidemicity are the same whether we find pathogenic organisms or not. His classification is as follows (1) acute dyspepsia due to food indiscretion, (2) acute gastro-enteritis in healthy children, (3) acute gastro-enteritis complicated by chronic dyspepsia, (4) symptomatic diarrhœa, in which diarrhœa is merely an incident in a disease outside the digestive system. During the summer months the first group passes into the second and third groups, there is no hard-and-fast division between them. I must say from my own personal experience during the last three years I find this classification very helpful.

As regards diagnosis, we must, of course, be quite sure that we are not dealing with some septic focus which will often cause diarrhœa in a child, such as discharging ears, empyema, pyelitis, &c. Overfeeding is the commonest exciting cause of summer diarrhœa. Other causes, such as contamination of food-supply, bad hygienic surroundings, overclothing must also be considered as contributory causes. A child will often cry and become restless in hot weather because it wants a drink of water so as to make good the loss of fluid by perspiration, instead of giving water the mother gives a drink of milk, thus the condition of overfeeding is made worse. A child in hot weather requires less food than it was having in cool weather. When the next feeding-time comes round the mother, thinking that the child is hungry because it is fretful, gives another feed of milk, and so the condition is made worse and Nature brings relief by causing vomiting and diarrhœa. The loss of fluid from the body very rapidly produces a condition of dehydration, and unless this dehydration is promptly relieved the child may die from this cause alone before the stage of intoxication is reached with high temperature. I felt certain that if we got hold of the case during the early stage there would be some hope for treatment to be effective.

Notification

Zymotic enteritis has been a notifiable disease for some years in seven of the London boroughs, but treatment by the health authority has not been suggested in any part of England or Wales. The administrative side of the work was in the hands of Dr J Fenton, the medical officer of health. Zymotic enteritis was made a notifiable disease for children under the age of 5 years on July 1st, 1924.

Directly the notification was received a health visitor called at the home and took notes of the case on a card specially prepared for the purpose. If the patient was already under the care of a medical practitioner and he wished to continue attending and did not require any nursing assistance, nothing further was done. If, however the visitor found that the doctor in attendance wished to have some nursing help, the visitor would telephone to the District Nursing Association, asking them to send someone immediately, and the nurses under these conditions would carry out the doctor's orders. Sometimes the practitioner would prefer to hand over the case to the officers working under the council. Other cases occurred where no doctor was in attendance or likely to be because the parents could not pay a fee. My services were requisitioned during the summer months to see all notified cases who were not receiving medical attention. The administration was therefore simple and worked admirably. There have been no complaints from medical practitioners in the neighbourhood, in fact, during the last year several doctors have asked the nurses to carry out the routine treatment in many of their cases. The district nurses tell me that during the last year the great majority of the cases have been notified within the first 24 hours of the commencement of the disease.

Symptoms

The disease began in the usual way quite suddenly with vomiting and diarrhœa. The children attacked could, roughly, be divided into two classes (1) those apparently quite healthy, and (2) the ill-nourished child under weight for its age, and already suffering from chronic digestive disturbance. The degree of collapse was usually dependent on the frequency of vomiting. The sunken eyes, depressed fontanelle, and scaphoid abdomen and restlessness were well immunity to diphtheria, that a previous attack of diphtheria or prophylaxis does not always give a negative reactor although it confers immunity, that repeated throat-swabs are necessary, that a virulence test is required to clear up all carriers, and that a school population can be dealt with safely and with little disturbance of school routine

---

AN UNUSUAL COMPLICATION OF MASTOIDITIS

By F W Watkyn-Thomas, B Ch Camb,
F R C S Eng,
SURGEON TO THE CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL

The three following cases illustrate a *complication* of mastoiditis that adds considerably to the difficulties of diagnosis

Differential Diagnosis

The diagnosis between mastoiditis and furuncle of the meatus is usually easy, but if the pus from the mastoid breaks through the posterior bony wall of the meatus and pushes the *membranous* lining forwards into the meatal lumen the signs and symptoms of a furuncle will be imitated, the meatus is blocked by a tender swelling, the membrane cannot be seen, there is tenderness on pressing the tragus or moving the pinna, and there may be pain during mastication At the same time the "classical signs" of mastoiditis (which, like most classical *signs*, are evidence of advanced disease) may be absent, partly because the pus has already made exit deeply, partly because of factors to be considered later, there is little tenderness or swelling over the mastoid process, and, as the pus lies behind the meatus, which can yield to the pressure, there will not be the deep, boring pain usually associated with mastoiditis For the same reason the swelling is not so tender or so painful as a true furuncle, which is confined to the tightly bound skin of the meatal wall This is the first point that should give a hint as to the true nature of the condition

The second point in the diagnosis is that the swelling, at first at any rate, is deeper in the meatus than a *furuncle* has any right to be, for a furuncle is an infection of the meatal sebaceous glands, and *these do not* extend beyond the cartilaginous meatus The third point is that the patient is more obviously a sick man than he should be from the apparent condition

Clinical Histories

CASE 1—A German prisoner-of-war aged 37. Four days "earache" following a severe cold The meatus was blocked by a tender fluctuating *swelling* It was rather deep, and not quite as tender as a furuncle usually is, but there was pain on mastication, pain on compressing the tragus or moving the pinna, no mastoid tenderness or œdema Temp 100° F, pulse 98 The abscess was opened and pain was relieved, but the temperature did not settle, and three days later there was still a free discharge, and the patient looked a very sick man The membrane could not be seen Hearing was slightly diminished, but *not more* so than could have been explained by the meatal blockage The mastoid was explored and a deep, high antrum, full of pus, was discovered There was an overlapping middle fossa and a forward lateral sinus From a cell below the antrum a fistulous tract opened through the posterior meatal wall The membrane appeared to be intact He recovered with normal hearing

CASE 2—A business man aged 30 A vague history of "earaches" in childhood and a week's history of pain in the right ear A tender, fluctuating swelling—except that it lay rather deeply and was not quite as tender as usual, a typical furuncle—partially occluded the meatus The membrane could not be seen fully, but appeared intact There was no mastoid tenderness, no deafness (low tone limit 16 d v), *and normal temperature* As he was very anxious to return to his work I opened the abscess under local anæsthesia He felt considerable relief, and when he returned to be dressed next day said he was quite comfortable Three days later, *when sitting* in a chair, he had a severe attack of vertigo and fell on to his left side. He went to bed and was seen by me the next day. The temperature and pulse were normal, there was no tenderness over the mastoid, but he had all the signs of a labyrinth fistula It was quite clear that there must be some deep extension so the mastoid was explored The antrum was deep and high, the middle fossa overlapped, and there was a fistula from a cell below the antrum through the posterior meatal wall In the antrum itself there was a small cholesteatoma which had eroded the torus of the horizontal canal Gentle pressure with wool on the erosion caused typical forced movements of the eyes As the cholesteatoma did not extend into the attic there was no need to do more than drain the antrum The patient recovered with normal hearing, and the labyrinth fistula gave no further trouble When the swelling of the meatus subsided the membrane appeared intact except for one doubtful area that might have been an old scar

CASE 3—A boy aged 12 Pain and swelling in the ear with discharge When he was seen, within 24 hours of the attack, there was a swelling *in the meatus near the roof* and rather deep Pus was exuding from this Temp 100 2° F, pulse 90 No swelling over the mastoid, although there was a definite history of a transient swelling in the early stage of the attack that had pushed the ear forward, very slight mastoid tenderness The position of the meatal swelling aroused suspicions, and when it was incised rough bone could be felt with a probe The mastoid was explored The apical cell was perfectly clear, *the cells above it were* filled with blood-stained fluid and laked pus, the bone was softened, and a track was found through the posterior meatal wall There was a high, deep antrum full of blood-stained fluid with a thickened, necrotic lining He made a good recovery with intact hearing, but there was some difficulty in getting complete healing of the operation incision It eventually yielded to two doses of ionisation by Mr T B Jobson There was an old, *healed scar on the* membrane

Commentary

The three cases have these points in common: 1 A mastoid infection without evidence of concurrent acute otitis media 2 A fistula through the posterior bony wall of the meatus 3. A high and deep antrum In every case the pus reached the meatus through the cells below the antrum, the route described by Lermoyez, who points out that this chain of cells, the "cellules limitrophes," is the most constant of all the groups

With regard to the integrity of the membrane in these three cases it is interesting to note that in a recent series of 18 cases of acute mastoiditis without middle-ear symptoms described by Beeger there was necrosis of the posterior wall in *four, and in four* others there was sufficient swelling of the meatus to render the membrane invisible.

MASSIVE COLLAPSE OF THE LUNGS

COMPLICATING A CASE OF ACUTE MENINGITIS.

By Norman Kletz, M B, Ch B Manch,
M R C P Lond,
PHYSICIAN, ANCOATS HOSPITAL, MANCHESTER, PHYSICIAN AND HON PATHOLOGIST, STOCKPORT INFIRMARY

The following case is interesting owing to the relative rarity of the condition

The patient, a well-developed and previously healthy young man aged 18, was seen in consultation with Dr C Moffatt, of Irlam, on Oct 30th, 1926

He had been perfectly well until the previous Wednesday, when he was seized with severe pain in the head On Thursday he got up, but did not go to work, and on Friday there developed pain in the back of the neck, and the patient felt that he was unable to "rise *or do* anything" During the later part of Friday and on Saturday morning some difficulty in breathing developed, which was accentuated by any attempt at movement and by coughing This difficulty was described by the patient as a feeling as though the chest were being tightly gripped During Friday and Saturday the temperature was between 100° and 101° F

I saw him about 4 P M. on Saturday He was lying comfortably on his back with the head partially raised on pillows There was marked cyanosis of the face and lips, and evident respiratory *embarrassment* of moderate degree The mentality was clear, the temperature was 101 1°, the pulse 126, and quite regular There was have begun to realise the importance of early notification and absolute starvation

The Health Visitors' Notes, 1924–26.

The number of cases visited was 216 Of these cases 119 were under 1 year of age, and 97 were 1 year and over The number of families in which the patient was the only case was 197 The number of families in which more than one case occurred was 11 The number of healthy children attacked was 129 Children who were under the normal weight for their age and suffering from chronic digestive disturbances numbered 66

Food on which the Children were Fed—Breast only, 33, breast and Nestlé's, 5; breast and Cow and Gate, 2, breast and Ambrosia, 3, breast and Glaxo, 1, breast and cow's, 5, breast and Robb's biscuit, 1, cow's milk and Ambrosia, 1, Nestlé's milk, 13, cow's milk, 51, Glaxo, 6, mixed diet, 75, Ambrosia, 1; Almata, 1, Allenbury, 1, Cow and Gate, 1 Mixed diet means that a child was having ordinary food, consisting generally of three meals of cow's milk, crust or bread-and-butter, and a midday meal of gravy and bread or potatoes and milk pudding The ages would vary from 8 months to 2 or 3 years

Infection

The question whether these cases infect one another has often been raised On examination of the present series it would appear that the great majority were not infective, but in some instances where there were several cases in the same house or the same family, and particularly when death occurred, there is a chance of infection having been conveyed by fæcal matter An interesting paper on the communication of diarrhœa from the sick to the healthy was read before the Epidemiological Section of the Royal Society of Medicine by Dr J E. Sandilands, the former medical officer of health for Kensington, in 1909 He gave evidence in his paper amounting to proof that certain fatal forms of summer diarrhœa are communicable Nevertheless, he says·

> "Communicability is by no means a conspicuous feature of epidemic diarrhœa in every case Thus in 19 out of 35 tenement houses in Kensington where deaths were registered as due to diarrhœa no other cases occurred Again, in 25 out of 35 fatal cases of diarrhœa no source of infection was found in the families occupying the houses where these patients died And, lastly, in 22 families containing young children fatal diarrhœa occurred, and yet in these families 44 parents and 58 children were intimately exposed to infection without falling ill In five hospitals there is no evidence of the spread of diarrhœa from patient to patient, and the sum of the evidence suggests that diarrhœa is not more infectious than typhoid fever, and is not conveyed except by the same channels"

In order to obviate contamination of food the mothers were told to wash their hands after touching soiled napkins

Conclusions

1. I think I have shown that it is easy to organise a scheme for early treatment of zymotic enteritis in large towns, and so relieve the pressure on our hospitals and reduce the number of moribund cases sent to these institutions 2 The results of early treatment are excellent, and the return to normal feeding is made far easier if the case is seen and treated early 3 I think this scheme may prove to be a useful addition to the public health service of the country

I am greatly indebted to the District Nursing Association of Kensington for their enthusiasm in their work, also to the official health visitors and superintendents of infant welfare centres

THE SCHICK TEST IN SCHOOL PRACTICE

By WILLIAM DUNN, M B, C M ABERD,
F H WALLACE, F R C S EDIN,
AND
A R BEAUMONT, F R C S EDIN,
UPPINGHAM

In a small outbreak of clinical diphtheria occurring in a school-house, when three boys and the matron were affected, the source of the outbreak was traced to a boy who had been at home on leave, and while there had associated with an established diphtheria contact, whose throat-swab was reported negative A swab from the throat of the returned boy was reported negative on March 31st, positive on April 8th. Thirty-five boys, aged between 14 and 18 years, and 15 adults were then submitted to the Schick test (Burroughs Wellcome outfit), but no attempt was made to immunise the contacts with toxin-antitoxin mixture

Case	Date of previous—		Schick test March 31	Result of throat swab		
	Attack	Prophylactic treatment		March 31	April 8	April 13
1	1921		–	+	–	–
2	1920		+	+	–	–
3	1921		–	–	–	
4	1904		–	–	–	
5	1899		+	–	–	
6		1921	+	–	–	
7		1922	+	–	–	
8		1912	–	–	–	
9		1914	–	–	–	

All 50 were injected concurrently, 1 minim of freshly diluted toxin being injected intradermally over the flexor aspect of the left forearm, a similar injection of sterilised toxin in the right forearm serving as control Throat-swabs were taken at the same time The arms were inspected 72 and 96 hours later In 19 cases the Schick reaction was positive, in 26 cases negative, and in 5 cases dubious Five boys gave a history of previous diphtheritic infection and four of prophylactic treatment

(Cases 1 and 2 in which the throat-swabs were positive had been in close contact with the clinical cases)

Of the 19 positive reactors, 5 had positive throat swabs, in 1 the first swab was negative and the second positive, 1 was sent home at the request of the parents, in 3 the organisms were found to be avirulent Two of these cases having chronic follicular tonsillitis, all were repeatedly found clear of diphtheria bacilli after the second swab

Of the 31 negative reactors, 7 (of whom 3 were in close contact with the clinical cases) had positive throat-swabs, 6 had no further positive swabs after seven days and repeated investigations, in 1 the organisms were found to be avirulent

The negative reactors with negative throat-swabs were sent back to school The positive reactors with negative throat-swabs were each given 1500 units of antidiphtheria serum The positive reactors with positive throat-swabs were given 6000 units of serum and were isolated until two throat-swabs had proved negative, a virulence test being done if the third was positive There were no further cases

The lessons to be drawn from this small outbreak are that the Schick test is reliable for determining but a stage of mesenteric gland tuberculosis Preceding the ascitic stage he believed there was a miliary condition, when the peritoneum was invaded by minute nodules perhaps in the absence of fluid. The adhesive type he looked upon as that of repair, and if this were so it set a definite limit to the scope of operative treatment Miliary tuberculosis in the peritoneum was only revealed at an operation for relieving pain for which the appendix had been held responsible. Then the correct treatment could be started, thus justifying the operation. Operation for ascites was also legitimate, and had been successful many times, but agreement had not been reached as to whether the operation was really curative or only hastened the adhesive stage The latter was not likely to be improved by laparotomy, if operation were done the intestine might be found adherent to the parietal peritoneum and thus liable to be injured, while the handling of the gut and the disturbance of adhesions might result in a fæcal fistula Operation should only be done to relieve emergency; many cases did well if left alone, and improvement was said to ensue from artificial sunlight

Tuberculous Enteritis.—In two of his cases of tuberculous enteritis obstruction had occurred; in all the ulceration was multiple. There was support for the view that ulceration took place in patients who already had pulmonary tuberculosis and swallowed their sputum. The prognosis was poor His three cases of ileo-cæcal tuberculosis were all in adults of ages 27 23, and 51, and in all of them it took the hyperplastic form The patients did well after a block resection of the affected area, but one died 17 months later of pulmonary tuberculosis

Tuberculous Appendicitis.—His one case of this condition was of the hyperplastic type, and only microscopical examination disclosed its nature In the ulcerative form the mucosa may be affected without the other coats being thickened

Tuberculous Mesenteric Glands—Mr Carson said he still retained the views he expressed in a paper read before the Medical Society in 1918 on the subject of tuberculous glands in the mesentery, and they had received confirmation from America and elsewhere The pain, he maintained, was due to spasm of the circular muscle coat, when mesenteric glands were tuberculous and there was no complication there was no rise of temperature Sepsis in this condition was unusual; that would cause pyrexia The average age of his 52 cases was 13 9 years, the oldest being aged 51 The sexes were about equally affected Except for pain the *only common* symptom was vomiting, which occurred in half the cases Disorders apt to be confused with mesenteric gland tuberculosis were colic from dietetic errors, relapsing appendicitis, intestinal worms, and ureteric stone Colic came on in infrequent attacks and was relieved by vomiting and by action of the bowels Relapsing appendicitis was accompanied by greater illness, furred tongue, increase of temperature and pulse-rate, flatulence nausea and constipation, pain lasted longer and was more localised, and there might be rigidity and tenderness on examination. Worms could only be diagnosed with certainty by finding them in the stools In ureteric stone the X rays enabled a diagnosis to be made if a ureteric bougie could be passed · even if it could not the shape of the shadow was quite distinct from that of a calcareous gland Urinary symptoms might give some help With regard to complications, he had noted that intussusception occurred only in the non-caseating type in his cases and obstruction in the caseating Of his 19 non-caseating cases which recovered ten remained quite well two had occasional pain still one had pulmonary tuberculosis and was in poor health, one died of that disease, and five had not been traced Of the 18 cases which had caseation and survived 13 remained quite well 2 had occasional pain 3 were untraced Of the 10 calcareous cases which recovered 5 were quite well, 1 had occasional pain, and the others were untraced

Mr. Carson, therefore, submitted that tuberculous disease of mesenteric glands was a serious condition, with a high mortality. and in later stages demanded elaborate surgery. His impression was that fewer cases of abdominal tuberculosis were being seen now than formerly, and he suggested two explanations for this reduction One was that modern medical treatment resulted in a cure of more cases, and the other that since the war the children as a whole were better fed, housed, and clothed and hence were better equipped for resisting infection If the milk-supply could be controlled an enormous step forward would result, but the necessary legislation seemed difficult of enactment.

Discussion.

Mr ZACHARY COPE said that, excluding genito-urinary tuberculosis and psoas abscess associated with active spinal caries, there remained three forms of the disease under discussion—glandular, intestinal. peritoneal The most common group of glands to be affected was the ileo-cæcal It was quite usual to find calcified glands in people who were apparently healthy. In the intestine the lesion might take the form of an ulcer eating deeply into the bowel wall and its cicatrisation might result in a stricture. Cæcal tuberculosis usually took the hypertrophic form. The peritoneum might be affected by miliary tubercles forming on the serous aspect of an ulcer of the bowel. If these tubercles were widely spread the peritoneum might be found thickened, even to half an inch, and in such cases fluid was often poured out In later stages a combination of conditions formed a very serious picture Usually abdominal tubercle was associated with deteriorated general health, and when this was progressive the possibility of the presence of tubercle must be considered

Mr. Cope mentioned seven manifestations of the disease as the surgeon saw them. Colicky pains might be the only symptom complained of; they were short, often severe. and might be accompanied by retching or vomiting The pains were not confined to one spot; there might be fever too If localised to the right iliac fossa exploration was desirable, as the condition might be appendicitis. A tumour might be evident, formed by large fleshy glands, rolled-up omentum, or hypertrophied cæcal tuberculosis Intussusception or neoplasm might be simulated If the tumour was formed of caseous glands there were usually other signs of tubercle also A skiagram might reveal calcified glands Adhesion to a calcified gland was a common cause of acute intestinal obstruction. The relief of this obstruction might be very difficult as the adherent coil might be deep down at the back of the abdomen. Obstruction might also be due to a tuberculous stricture Intestinal ulceration led to diarrhœa. When a fæcal fistula formed it was usually in the region of the umbilicus Peritonitis due to a perforation into the general peritoneal cavity was usually a fatal complication, as the patient was already debilitated by the primary lesion. It might be a result of an acute miliary invasion of the peritoneum, without any ulceration having occurred, and when this was so the prognosis was somewhat more hopeful. Ascites resulted from a subacute miliary infiltration of the peritoneum. It could generally be diagnosed by considering the history, the general aspect, and the local condition; but mistakes were possible. For example, he had known in a child. aged 6, a large hydronephrosis, extending from diaphragm to pelvic floor, mistaken for tuberculous ascites In adults it was often difficult to distinguish between cancerous and tuberculous peritonitis, in cases in which he was in doubt the condition had always proved to be cancerous

Indications for surgical interference in cases of abdominal tuberculosis Mr Cope set out as follows: (1) to let out the ascitic fluid, which usually was poor in protective substances; (2) to remedy the intestinal obstruction, (3) to suture perforations and drain septic peritonitis; (4) occasionally to remove slight retraction of the head, and any attempt at passive movement produced severe pain extending down the neck into the back Kernig's sign was positive on both sides, and in eliciting it severe pain was complained of extending right up the back Brudzinski's sign was negative The right pupil was somewhat larger than the left, but both pupils were regular in outline, and reacted normally to light and to accommodation The abdominal reflexes were absent on both sides, as were the knee-jerks The plantar response on the right side was definitely flexor, on the left side there was no actual movement of the toes on the application of a stimulus, but there was evident contraction or tightening of the hamstring tendons There was no evidence of papillœdema There were no cranial nerve palsies No sensory disturbance was discovered On examination of the chest the heart was found to be markedly displaced to the right side, the impulse extending beyond the right mid-clavicular line Movement was somewhat restricted over the right side, but there was no definite flattening, or recession of the chest wall Percussion note was resonant everywhere, and the breath sounds were everywhere vesicular but somewhat diminished over the right base No adventitious sounds were heard at this examination, but Dr Moffatt informed me that at periods there had been well-marked generalised râles The liver was on the right side

The absent abdominal reflexes and the absent knee-jerks, combined with apparent slight involvement of the pyramidal path to the left side, indicated the presence of some organic nervous disease The predominance of pain in the head and neck, together with the retraction, suggested that the meninges were involved, the abrupt onset, the pyrexia and tachycardia, supported an acute inflammatory process as the probable nature of the pathological change The diagnosis was that of acute meningo-encephalitis

The question then arose as to the interpretation of the dextrocardia In view of the fact that there was no transposition of the viscera, and in view of the obvious respiratory embarrassment, it seemed almost certain that the cardiac displacement was acquired and not congenital There was clearly nothing at the left side of the chest in the nature of a pneumothorax or pleural effusion to account for such displacement, nor was there any evidence of gross fibrosis on the right side which might have led to active dragging over of the heart to that side The conclusion, therefore, to which I came was that there probably existed massive collapse of the right lung, especially of its basal lobe, and it seemed to me that this was strongly supported by the apparently abrupt, or, at any rate, rapid development of the displacement

The patient was transferred to Ancoats Hospital for further investigation and treatment Several attempts were made to perform lumbar puncture, but on each occasion such marked respiratory embarrassment was produced as to render it impossible, and in view of the lung condition an anæsthetic seemed out of the question For the next 12 hours or so the position was more or less stationary, with occasional paroxysms of increased dyspnœa accompanied by temporary accumulation of secretion in the lungs During the early part of Sunday afternoon the heart was noticed to be receding towards the left, and, coincident with this, the patient's condition grew worse This change in the position of the heart was attributed to collapse developing in the left side of the chest The patient died at 5 P.M.

Post-mortem Examination—I performed a necropsy on Nov 1st The body was well developed and rigor mortis was still present There was no external evidence of injury or disease, though there was still cyanosis of the face On opening the thorax no air escaped. The heart occupied a normal position but was unduly exposed, both the lungs were markedly collapsed, and this was especially evident in the case of the basal lobes, which were shrunken up against the vertebral column, completely exposing both cupolæ of the diaphragm. Each pleural sac contained a few ounces of fluid The lungs themselves were firm and somewhat leathery in consistency, especially the right lower lobe, which was almost completely airless, and did not float in water Otherwise the lungs were normal The heart showed no gross abnormality with the exception of a few punctate subepicardial hæmorrhages There was slight fatty change in the aortic intima close to its root The liver and kidneys showed cloudy swelling, the adrenal cortex showed the pallor so frequently associated with severe infections The spleen was not enlarged, was of moderate consistence, and showed no gross naked-eye change The brain was intensely injected, but there was no exudate on the surface and no meningeal hæmorrhages Naked eye, the spinal cord showed no apparent change

Swabs were taken from cerebral sulci in several situations Culture of this material yielded a very free growth of Gram-negative diplococci identified as meningococci, together with a very long-chained hæmolytic streptococcus

Commentary

Massive collapse of the lung is a condition in which there is abrupt, or rapid collapse of the whole or a large area of a lung occurring without any primary intrapleural or pulmonary cause—e g, pneumothorax, pleural effusion, hæmothorax, bronchial obstruction, &c The condition was originally described by W Pasteur, who defined it as "a total deflation of a large area of lung tissue of sudden onset, due to failure of respiratory power." The cases upon which the original description was based were cases of paralysis of the diaphragm, arising from post-diphtheritic neuritis The majority, however, have occurred apart from this condition, and especially in association with trauma, either to the same or opposite side of the thorax or to some more distant part This type has been termed the reflex type, and has been particularly described by Sir John Rose Bradford as a result of gunshot wound. Cases are also described occurring as a sequela of abdominal operations, and, occasionally, the condition may arise as a complication of pneumonia and pleurisy The exact mechanism of the production of the condition, especially in the reflex type, is by no means clear, whether it be the result of diaphragmatic paralysis or contraction of the bronchial muscle, and resultant cutting off of the air entry to the affected area of lung

The interesting features of the case here described appear to be. 1 The occurrence of massive collapse of the lungs in association with acute meningitis 2 The possible explanation of the collapse, whether of the primary paralytic type due to involvement of the cervical cord or whether reflex in origin 3 The paucity of physical signs of collapse other than the cardiac displacement 4 The mixed meningococcal and streptococcal infection

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

AT a meeting of this Section held on Jan 5th, Mr V WARREN LOW, the President, occupying the chair, Mr H W. CARSON opened a discussion on

ABDOMINAL TUBERCULOSIS

This condition, he said, as seen by the surgeon did not show many varieties, but missing or unusual symptoms might cause diagnostic difficulties, and the state of things revealed after an incision had been made often placed a strain on the surgeon's skill and experience In the last eight years he had operated on only five cases of tuberculous peritonitis, four of tuberculous enteritis, three of ileo-cæcal tubercle, one of tuberculous appendicitis, and 52 cases of tuberculosis of mesenteric glands In some of the instances the operation was urgent, usually to relieve obstruction His series did not support the current belief that abdominal tuberculosis was an affection of childhood The disease in the mesenteric glands showed the youngest age-incidence—65 per cent 5–15 years of age, 17 per cent over 25, two of them as old as 50 and 51 Tuberculous enteritis (including ileo cæcal) was a disease of middle life It was not usual for mesenteric gland tubercle to be associated with pulmonary tuberculosis nor for tuberculous peritonitis to be so allied, though tuberculous enteritis and lung disease often coexisted

Tuberculous Peritonitis—Mr Carson asked whether tuberculous peritonitis was ever primary or whether it might not be borne by the blood from some remote focus—pulmonary, mediastinal, tubal, or mesenteric Three forms were described—ascitic, adhesive, caseous The last-named, he submitted, had a different ætiology from the other two kinds, being, he considered, but a stage of mesenteric gland tuberculosis. Preceding the ascitic stage he believed there was a miliary condition, when the peritoneum was invaded by minute nodules, perhaps in the absence of fluid. The adhesive type he looked upon as that of repair, and if this were so it set a definite limit to the scope of operative treatment. Miliary tuberculosis in the peritoneum was only revealed at an operation for relieving pain for which the appendix had been held responsible. Then the correct treatment could be started, thus justifying the operation. Operation for ascites was also legitimate, and had been successful many times, but agreement had not been reached as to whether the operation was really curative or only hastened the adhesive stage. The latter was not likely to be improved by laparotomy: if operation were done the intestine might be found adherent to the parietal peritoneum and thus liable to be injured while the handling of the gut and the disturbance of adhesions might result in a fæcal fistula. Operation should only be done to relieve emergency; many cases did well if left alone, and improvement was said to ensue from artificial sunlight.

Tuberculous Enteritis.—In two of his cases of tuberculous enteritis obstruction had occurred: in all the ulceration was multiple. There was support for the view that ulceration took place in patients who already had pulmonary tuberculosis and swallowed their sputum. The prognosis was poor. His three cases of ileo-cæcal tuberculosis were all in adults of ages 27, 23, and 51, and in all of them it took the hyperplastic form. The patients did well after a block resection of the affected area, but one died 17 months later of pulmonary tuberculosis.

Tuberculous Appendicitis.—His one case of this condition was of the hyperplastic type, and only microscopical examination disclosed its nature. In the ulcerative form the mucosa may be affected without the other coats being thickened.

Tuberculous Mesenteric Glands.—Mr. Carson said he still retained the views he expressed in a paper read before the Medical Society in 1918 on the subject of tuberculous glands in the mesentery, and they had received confirmation from America and elsewhere. The pain, he maintained, was due to spasm of the circular muscle coat: when mesenteric glands were tuberculous and there was no complication there was no rise of temperature. Sepsis in this condition was unusual: that would cause pyrexia. The average age of his 52 cases was 13.9 years, the oldest being aged 51. The sexes were about equally affected. Except for pain the only common symptom was vomiting, which occurred in half the cases. Disorders apt to be confused with mesenteric gland tuberculosis were colic from dietetic errors, relapsing appendicitis, intestinal worms, and ureteric stone. Colic came on in infrequent attacks and was relieved by vomiting and by action of the bowels. Relapsing appendicitis was accompanied by greater illness, furred tongue, increase of temperature and pulse-rate, flatulence, nausea, and constipation; pain lasted longer and was more localised, and there might be rigidity and tenderness on examination. Worms could only be diagnosed with certainty by finding them in the stools. In ureteric stone the X rays enabled a diagnosis to be made if a ureteric bougie could be passed: even if it could not, the shape of the shadow was quite distinct from that of a calcareous gland. Urinary symptoms might give some help. With regard to complications, he had noted that intussusception occurred only in the non-caseating type in his cases and obstruction in the caseating. Of his 19 non-caseating cases which recovered, ten remained quite well, two had occasional pain still, one had pulmonary tuberculosis and was in poor health, one died of that disease, and five had not been traced. Of the 18 cases which had caseation and survived, 13 remained quite well, 2 had occasional pain, 3 were untraced. Of the 10 calcareous cases which recovered, 5 were quite well, 1 had occasional pain and the others were untraced.

Mr. Carson therefore submitted that tuberculous disease of mesenteric glands was a serious condition, with a high mortality, and in later stages demanded elaborate surgery. His impression was that fewer cases of abdominal tuberculosis were being seen now than formerly, and he suggested two explanations for this reduction. One was that modern medical treatment resulted in a cure of more cases and the other that since the war the children as a whole were better fed, housed, and clothed, and hence were better equipped for resisting infection. If the milk-supply could be controlled an enormous step forward would result, but the necessary legislation seemed difficult of enactment.

Discussion.

Mr. ZACHARY COPE said that excluding genito-urinary tuberculosis and psoas abscess associated with active spinal caries, there remained three forms of the disease under discussion—glandular, intestinal, peritoneal. The most common group of glands to be affected was the ileo-cæcal. It was quite usual to find calcified glands in people who were apparently healthy. In the intestine the lesion might take the form of an ulcer eating deeply into the bowel wall and its cicatrisation might result in a stricture. Cæcal tuberculosis usually took the hypertrophic form. The peritoneum might be affected by miliary tubercles forming on the serous aspect of an ulcer of the bowel. If these tubercles were widely spread the peritoneum might be found thickened, even to half an inch, and in such cases fluid was often poured out. In later stages a combination of conditions formed a very serious picture. Usually abdominal tubercle was associated with deteriorated general health, and when this was progressive the possibility of the presence of tubercle must be considered.

Mr. Cope mentioned seven manifestations of the disease as the surgeon saw them. Colicky pains might be the only symptom complained of: they were short, often severe, and might be accompanied by retching or vomiting. The pains were not confined to one spot: there might be fever too. If localised to the right iliac fossa exploration was desirable, as the condition might be appendicitis. A tumour might be evident, formed by large fleshy glands, rolled-up omentum, or hypertrophied cæcal tuberculosis. Intussusception or neoplasm might be simulated. If the tumour was formed of caseous glands there were usually other signs of tubercle also. A skiagram might reveal calcified glands. Adhesion to a calcified gland was a common cause of acute intestinal obstruction. The relief of this obstruction might be very difficult as the adherent coil might be deep down at the back of the abdomen. Obstruction might also be due to a tuberculous stricture. Intestinal ulceration led to diarrhœa. When a fæcal fistula formed it was usually in the region of the umbilicus. Peritonitis due to a perforation into the general peritoneal cavity was usually a fatal complication, as the patient was already debilitated by the primary lesion. It might be a result of an acute miliary invasion of the peritoneum, without any ulceration having occurred, and when this was so the prognosis was somewhat more hopeful. Ascites resulted from a subacute miliary infiltration of the peritoneum. It could generally be diagnosed by considering the history, the general aspect, and the local condition: but mistakes were possible. For example, he had known in a child, aged 6, a large hydronephrosis, extending from diaphragm to pelvic floor, mistaken for tuberculous ascites. In adults it was often difficult to distinguish between cancerous and tuberculous peritonitis; in cases in which he was in doubt the condition had always proved to be cancerous.

Indications for surgical interference in cases of abdominal tuberculosis Mr. Cope set out as follows: (1) to let out the ascitic fluid, which usually was poor in protective substances; (2) to remedy the intestinal obstruction: (3) to suture perforations and drain septic peritonitis; (4) occasionally to remove slight retraction of the head, and any attempt at passive movement produced severe pain extending down the neck into the back. Kernig's sign was positive on both sides, and in eliciting it severe pain was complained of extending right up the back. Brudzinski's sign was negative. The right pupil was somewhat larger than the left, but both pupils were regular in outline, and reacted normally to light and to accommodation. The abdominal reflexes were absent on both sides, as were the knee-jerks. The plantar response on the right side was definitely flexor; on the left side there was no actual movement of the toes on the application of a stimulus, but there was evident contraction or tightening of the hamstring tendons. There was no evidence of papillœdema. There were no cranial nerve palsies. No sensory disturbance was discovered. On examination of the chest the heart was found to be markedly displaced to the right side, the impulse extending beyond the right mid-clavicular line. Movement was somewhat restricted over the right side, but there was no definite flattening, or recession of the chest wall. Percussion note was resonant everywhere, and the breath sounds were everywhere vesicular but somewhat diminished over the right base. No adventitious sounds were heard at this examination, but Dr. Moffatt informed me that at periods there had been well-marked generalised râles. The liver was on the right side.

The absent abdominal reflexes and the absent knee-jerks, combined with apparent slight involvement of the pyramidal path to the left side, indicated the presence of some organic nervous disease. The predominance of pain in the head and neck, together with the retraction, suggested that the meninges were involved; the abrupt onset, the pyrexia and tachycardia, supported an acute inflammatory process as the probable nature of the pathological change. The diagnosis was that of acute meningo-encephalitis.

The question then arose as to the interpretation of the dextrocardia. In view of the fact that there was no transposition of the viscera, and in view of the obvious respiratory embarrassment, it seemed almost certain that the cardiac displacement was acquired and not congenital. There was clearly nothing at the left side of the chest in the nature of a pneumothorax or pleural effusion to account for such displacement, nor was there any evidence of gross fibrosis on the right side which might have led to active dragging over of the heart to that side. The conclusion, therefore, to which I came was that there probably existed massive collapse of the right lung, especially of its basal lobe, and it seemed to me that this was strongly supported by the apparently abrupt, or, at any rate, rapid development of the displacement.

The patient was transferred to Ancoats Hospital for further investigation and treatment. Several attempts were made to perform lumbar puncture, but on each occasion such marked respiratory embarrassment was produced as to render it impossible, and in view of the lung condition an anæsthetic seemed out of the question. For the next 12 hours or so the position was more or less stationary, with occasional paroxysms of increased dyspnœa accompanied by temporary accumulation of secretion in the lungs. During the early part of Sunday afternoon the heart was noticed to be receding towards the left, and, coincident with this, the patient's condition grew worse. This change in the position of the heart was attributed to collapse developing in the left side of the chest. The patient died at 5 P.M.

Post-mortem Examination.—I performed a necropsy on Nov. 1st. The body was well developed and rigor mortis was still present. There was no external evidence of injury or disease, though there was still cyanosis of the face. On opening the thorax no air escaped. The heart occupied a normal position but was unduly exposed, both the lungs were markedly collapsed, and this was especially evident in the case of the basal lobes, which were shrunken up against the vertebral column, completely exposing both cupolæ of the diaphragm. Each pleural sac contained a few ounces of fluid. The lungs themselves were firm and somewhat leathery in consistency, especially the right lower lobe, which was almost completely airless, and did not float in water. Otherwise the lungs were normal. The heart showed no gross abnormality with the exception of a few punctate subepicardial hæmorrhages. There was slight fatty change in the aortic intima close to its root. The liver and kidneys showed cloudy swelling, the adrenal cortex showed the pallor so frequently associated with severe infections. The spleen was not enlarged, was of moderate consistence, and showed no gross naked-eye change. The brain was intensely injected, but there was no exudate on the surface and no meningeal hæmorrhages. Naked eye, the spinal cord showed no apparent change.

Swabs were taken from cerebral sulci in several situations. Culture of this material yielded a very free growth of Gram-negative diplococci identified as meningococci, together with a very long-chained hæmolytic streptococcus.

Commentary

Massive collapse of the lung is a condition in which there is abrupt, or rapid collapse of the whole or a large area of a lung occurring without any primary intrapleural or pulmonary cause—e.g., pneumothorax, pleural effusion, hæmothorax, bronchial obstruction, &c. The condition was originally described by W. Pasteur, who defined it as "a total deflation of a large area of lung tissue of sudden onset, due to failure of respiratory power." The cases upon which the original description was based were cases of paralysis of the diaphragm, arising from post-diphtheritic neuritis. The majority, however, have occurred apart from this condition, and especially in association with trauma, either to the same or opposite side of the thorax or to some more distant part. This type has been termed the reflex type, and has been particularly described by Sir John Rose Bradford as a result of gunshot wound. Cases are also described occurring as a sequela of abdominal operations, and, occasionally, the condition may arise as a complication of pneumonia and pleurisy. The exact mechanism of the production of the condition, especially in the reflex type, is by no means clear, whether it be the result of diaphragmatic paralysis or contraction of the bronchial muscle, and resultant cutting off of the air entry to the affected area of lung.

The interesting features of the case here described appear to be: 1. The occurrence of massive collapse of the lungs in association with acute meningitis. 2. The possible explanation of the collapse, whether of the primary paralytic type due to involvement of the cervical cord or whether reflex in origin. 3. The paucity of physical signs of collapse other than the cardiac displacement. 4. The mixed meningococcal and streptococcal infection.

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

AT a meeting of this Section held on Jan. 5th, Mr. V. WARREN LOW, the President, occupying the chair, Mr. H. W. CARSON opened a discussion on

ABDOMINAL TUBERCULOSIS

This condition, he said, as seen by the surgeon did not show many varieties, but missing or unusual symptoms might cause diagnostic difficulties, and the state of things revealed after an incision had been made often placed a strain on the surgeon's skill and experience. In the last eight years he had operated on only five cases of tuberculous peritonitis, four of tuberculous enteritis, three of ileo-cæcal tubercle, one of tuberculous appendicitis, and 52 cases of tuberculosis of mesenteric glands. In some of the instances the operation was urgent, usually to relieve obstruction. His series did not support the current belief that abdominal tuberculosis was an affection of childhood. The disease in the mesenteric glands showed the youngest age-incidence—65 per cent. 5–15 years of age, 17 per cent. over 25, two of them as old as 50 and 51. Tuberculous enteritis (including ileo-cæcal) was a disease of middle life. It was not usual for mesenteric gland tubercle to be associated with pulmonary tuberculosis nor for tuberculous peritonitis to be so allied, though tuberculous enteritis and lung disease often coexisted.

Tuberculous Peritonitis.—Mr. Carson asked whether tuberculous peritonitis was ever primary or whether it might not be borne by the blood from some remote focus—pulmonary, mediastinal, tubal, or mesenteric. Three forms were described—ascitic, adhesive, caseous. The last-named, he submitted, had a different ætiology from the other two kinds, being, he considered, abdomen and tuberculous epididymitis he would not fail to diagnose tuberculous peritonitis In the neck gland disease was always secondary. The resistance of these glands was diminished by some infection of the tonsil, and then tubercle was secondarily implanted on them, and he thought the same was true of the glands in the mesentery He agreed that not all these gland enlargements were necessarily tuberculous, if they had been he thought he would have seen a great many more cases than he had done

---

SECTION OF NEUROLOGY

At a meeting of this Section on Jan 13th Sir James Purves-Stewart took the chair, and Dr Aldren Turner, President of the Section, opened a discussion on

EPILEPSY

After summarising the features of various forms of epileptic manifestations, he drew attention to Rowse's attempt to broaden the aspect of epilepsy so as to include the psychic, the view of that worker being that epilepsy was the prototype of every functional nervous illness and that in certain phases of disturbed consciousness attributable to emotional causes there was a difficulty in separating epilepsy from other mental or psychic states The fact was, said Dr Turner, that there was no single clinical entity to which the name of epilepsy could be applied, and evidence was accumulating that the epileptic type of fit-reaction might result from mental as well as from physical causes Three groupings seemed possible (1) the organic, (2) the toxinfective or metabolic, and (3) the psychogenic, but there remained a great mass of residual cases which could only, at the present stage of knowledge be designated as "epilepsy of unknown origin" Any cerebral organic lesion might have as one of its symptoms seizures resembling an epileptic fit. When the cause was a trauma, epilepsy might not develop until four or five years after the accident, and there was an absence of any definite or constant relation between the region of the brain involved and the mode of onset of the major fit Clearly also, the fit was not due to any cerebral scarring Only about 5 per cent. of a large series of penetrating wounds of the head developed epilepsy, and there must therefore be something more than tissue changes at the seat of injury to account for traumatic epilepsy A case had been described by Foster Kennedy, in which the patient had a fit during an operation on the parietal cortex sudden blanching of the cortex was observed, followed quickly by venous engorgement and protrusion of the brain beyond the level of the bone defect, and this protrusion coincided in time with the period of the clonic convulsion The inherent instability of epileptic patients might be due to defect in the vegetative nervous system. Dr J S Collier favoured the toxic origin of epilepsy, and was able to make out a strong case. In some cases of epilepsy there was evidence, on other grounds, that the normal endocrine-balance was disturbed, but in Dr Turner's hands therapeutic measures based on endocrine therapy had given only negative results On the question of epilepsy of psychogenic origin, he said that there was difficulty in distinguishing the hysterical from the epileptic type of fit, especially when the patient was under psychical stress The question arose whether even an intensified emotion, without any other factor, would not suffice to produce an attack of major epilepsy Some patients derived benefit from psychotherapy, but there was reason for saying that psycho-analytic treatment had not had the effect which was expected of it He found it difficult to fix upon any special mentality in the case of all epileptic patients, but anxiety due to uncertainty as to when another fit might occur was a very important accompaniment In a few cases in which, after years of seizures, an arrest had been brought about, there had been a cessation of this anxiety and a re-establishment of the normal attitude towards life. Dr Turner proceeded to discuss the large group of cases of epilepsy of unknown origin. About 33 per cent of a large series showed heredity in regard to the malady, and in a small number of the remainder alcoholism might have caused injury to the germ-plasm, or there might have been some form of intoxication during intrauterine life

Discussion

Dr George Riddoch said that during the past two years investigation into this subject had been going on at the London Hospital Many questions about the disorder remained unsolved, notably the large question of the ætiology as well as the mechanism by which the seizure and the loss of consciousness were produced Dr Russell Brain had investigated 200 people (unselected) of the hospital class and had found that there was a hereditary history in 28 per cent, but taking into consideration the difficulty of getting accurate family histories, and the likelihood that small attacks of petit mal occurred without any significance having been attributed to them, the speaker thought that 28 per cent was far below the actual figure Convulsions in infancy were about twice as frequent in families with a hereditary history of epilepsy as in those without such a history Insanity had not been found to be more common in epileptics than in non-epileptics, but in epileptic families there was a greater proportion of epileptics amongst the first-born members than among those born later In the late war only 5 per cent of soldiers who had sustained head injuries were said to have had epilepsy, but this figure was probably well on the low side, because petit mal attacks had passed unrecognised In the investigations at the London Hospital a large proportion of the patients subject to attacks of petit mal had shown definite improvement on being allowed nothing but water for a fortnight, the fits either ceased within 48 hours of the beginning of starvation, or their frequency was greatly diminished and the benefit continued for some time after food was resumed He did not advocate this course as a therapeutic measure, the test had been made in view of claims which had been made Dr Riddoch referred to experiments which had been done with the object of securing a good convulsant with which results could be checked and repeated at will Cocaine gave better results than insulin A 1 per cent solution of cocaine injected into the marginal vein of the ear of the rabbit produced seizures in every way comparable with those in the human epileptic, the animals were unconscious and many of them had incontinence and a post-convulsive period of excitement Cats gave a different result with cocaine Thujol gave definite results, and work with this drug was being continued The intravenous injection of bromide had also been tried in increasing concentration The seizures had gradually diminished in severity and had finally been eliminated altogether

Dr Russell Brain referred to the biochemical work which had been done at the London Hospital and particularly to estimations of the blood-cholesterol of epileptics Cholesterol, he said, constituted one-eighth of the solids of the brain by weight, and it was thought there might be a relationship between epilepsy and the metabolism of cholesterol. In women there was an abrupt fall in the blood-cholesterol during the days immediately preceding menstruation; sometimes the amount fell to half the normal during the catamenia, and this was attributed by one worker to formation of the corpus luteum Women subject to epilepsy were most likely to have fits while their cholesterol was at its minimum Dr Brain showed a comparative table to demonstrate that on the average the figure for cholesterol was lower in epileptics than in normal people, whilst the maxima in both showed even greater differences In eight cases examined in this way it was found that an attack was preceded by a prolonged fall in the level of the blood-cholesterol, the observations were taken hourly After an attack the cholesterol content showed a substantial rise Cholesterol was a large fleshy glands which caused symptoms and could be enucleated without injuring mesenteric vessels, (5) to drain abscesses formed by the breaking down of caseous glands

DR MAURICE A CASSIDY expressed his agreement with Mr. Carson that tuberculous enteritis seemed to be less common of recent years than formerly; this he attributed partly to a diminished incidence of all forms of tuberculosis and the more general segregation of tuberculous patients in special hospitals and separate departments One result of this was a great loss of valuable clinical material to the general physician and the student Tuberculous peritonitis did not seem much diminished, but there was a change recently in the sex-incidence. In a series published by Osler there were 131 females to 60 males, whereas in a series at St Thomas's Hospital there were 54 males, 45 females He considered the outlook in uncomplicated tuberculous peritonitis uniformly good, he told his students that if they had to be infected with Koch's bacillus the site to select was the peritoneal cavity, as it gave the best chance of complete recovery without resultant disability In a series of 267 cases at St Thomas's the mortality was only 9 7 per cent and most of the fatal cases died from such conditions as perforation or obstruction, in some other viscera were involved Some young persons had abdomens which were symptomless yet were the seat of tuberculous tumours, and they had been seen to grow into healthy adult life after but little treatment. Pain in tuberculous peritonitis was a very variable symptom, it might be absent or of any degree of severity. Either constipation or diarrhœa might occur, the latter usually being associated with the passage of fatty stools, due probably to defective absorption following obstruction of lacteals by tuberculous mesenteric glands In the first 24 hours this peritonitis might be mistaken for appendicitis and surgical interference was harmless if the mesenteric glands were left alone. In adults the more chronic conditions might be confused with carcinoma, the presence or absence of pyrexia was not helpful either way, and there seemed no reason why a tuberculous patient should not develop carcinoma Cirrhosis of liver might be mistaken for tuberculous peritonitis, the former was sometimes met with even in young children It was agreed that simple laparotomy in tuberculous peritonitis produced a rapid improvement when progress had been slow on medical treatment Apart from this simple opening of the abdomen, the treatment of such cases should be on sanatorium lines, and he was quite satisfied as to the marked benefit produced by sunlight and by artificial light Probably intestinal tuberculosis was a more common early complication of pulmonary tuberculosis than was usually supposed It could be diagnosed at an early stage, and if efficiently treated recovery was by no means exceptional In a large series only 7 per cent were abdominal primarily, whereas in 80 per cent of fatal cases of the abdominal disease there was also pulmonary tuberculosis The number of tubercle bacilli found in specimens of the stools of patients seemed to be in direct relation to the quantity of bacilli-bearing sputum swallowed

The PRESIDENT, in a general review of the subject, said he agreed that what was termed caseous peritonitis was probably due to the bursting of, or the infiltration of the peritoneum by, a caseous gland, and in some cases the result was a fæcal fistula When he was seeing many children he found the mortality of these cases was very small Septic peritonitis was a much more serious disease and caused more intense illness than the peritonitis due to tubercle with ascites He did not agree with Mr Carson that adhesive peritonitis represented a healing form, he regarded these cases as very malignant, and operative attempts were apt to prove fatal. It was very common to see children with tuberculous mesenteric glands He ascribed the symptoms mentioned by Mr Carson as associated with tuberculous glands to cases in which there were mechanical complications connected with those glands, such as kinks or attachments And he had not seen intussusception except where glands were affected Frequently tuberculous peritonitis in the male was associated with tuberculous epididymitis

MR. CECIL ROWNTREE pointed out that Mr Carson's work on the clinical side had been confirmed by the experimental work of L R Braithwaite (Leeds) on kittens It was possible to meet with cases having tuberculous mesenteric glands as their only diagnosable disease The cases were not easily recognised, the children were infected at about 3 or 4 years of age, when they came under the care of physicians He believed all the cases had some increase of temperature during the actual period of invasion Afterwards they became better, but did not get well, they were weak and unable to absorb fats for the reason already given A surgeon was called later, either because complications had developed or at school age because there were attacks of pain, either following games or spontaneous Many cases were diagnosed as appendicitis, the appendix was removed, and sometimes the patients got better If they did not a skiagram was taken and revealed masses of calcified mesenteric glands which were probably responsible for the perpetuation of the symptoms When there were symptoms he considered it was the surgeon's duty to remove the glands

DR JOHN A RYLE dealt with the early recognition of mesenteric glandular tuberculosis For this early condition there was no reason for seeking the aid of the surgeon, as, given suitable environment and care, recovery ensued without him He stressed the loss of energy and initiative at this stage, remarking that if such a child wished to go to bed before his usual time it was a very suspicious sign of early tubercle The temperature would usually be found to be 99°–100° F, taken carefully in the rectum When pain was asked about, the child placed his hands on both iliac regions Associated with this was often a mild but very chronic diarrhœa, the stools being unformed rather than actually watery An adult with this condition had also severe anæmia, which was very helpful in diagnosis A skiagram of the chest would probably reveal suspicious shadows at the root of the lungs

MR W E TANNER supported Mr Carson's views If the symptoms were severe enough to call for laparotomy and large masses of calcified glands were found, it was important to excise those glands, he had usually found the enlargement localised to one group

MR MORTIMER WOOLF, speaking of ileo cæcal tuberculosis, said that two years ago he had under his care a man who had been operated on in another hospital, a tiny incision having been made over the anterior superior spine, and it was said the surgeon had merely put in a finger and then closed the wound Nine months later he was sent to the speaker as he had been having pain, and he found a large tumour, he thought probably due to ileo-cæcal tuberculosis He did a lateral anastomosis between the ileum and the ascending colon The man was now well, having lost his obstruction, but there was still some tumour there He, the speaker, wondered whether it was always necessary to do an extensive operation—whether a lateral anastomosis would not sufficiently answer the purpose And he raised the question whether the enlarged glands were always necessarily tuberculous, surely it was possible for the enlargement of some of them to be of inflammatory type On to the latter there might be tuberculous disease grafted subsequently

Reply

MR CARSON said that for a long time he thought with Mr Warren Low that pain meant complication, because in two cases within a short time spasm and intussusception took place before his eyes on the operating table But he now thought these cases had irritation of the nerve-supply to that portion of the gut, and that in consequence there was intense spasm of circular muscle-fibres If he found a weird over a crown sized area over the insertion of the deltoid There was marked deviation to the left of the spine of the seventh vertebra, constant in all positions, but without any pain, tenderness or limitation of movement Ophthalmoscopic examination suggested a past papillitis The Wassermann reaction was negative and the X ray films revealed nothing more than a diminution in the joint space between the fifth and sixth vertebræ, possibly due to the curvature

The only adequate explanation, said Dr Eastwood, appeared to be that there was rupture or stretching of the fifth cervical nerve at its junction with the sixth Operation was proposed

The PRESIDENT said that in his experience operations in cases such as this were very unfavourable Mr W H OGILVIE and Mr C P WAKELEY agreed, and remarked on the amazing extent to which recovery often took place after about a year's rest

Paresis of Hand with Cervical Rib and Sprengel s Shoulder

Dr SAXBY WILLIS and Mr OGILVIE showed a woman of 56 with radicular paresis on the right hand associated with abnormal bone formation of the seventh cervical vertebra and Sprengel's shoulder She had noticed for six years only an inability to extend the metacarpophalangeal joints There was wasting of the palmar interossei and reaction of degeneration in the common extensors, but no sensory changes The X rays showed very large transverse processes on the seventh cervical vertebra and a rudimentary first dorsal rib only on the right side They proposed to explore and see if the pressure on the seventh nerve-root could be relieved There might be fusion of two transverse processes narrowing its outlet

The PRESIDENT agreed that operation would be fully justified

Dr WEBER pointed out that the extensions on the seventh cervical vertebra corresponded with what was called the "short type" cervical rib, a type which was most often associated with paresis and symptoms which did not appear until the "early degenerative" stage of life when there was a tendency to kyphosis He did not think the case should be operated on

Acromegaly

Dr WILLIS showed a woman of 28 who had acromegaly of possible traumatic origin, with proliferative changes in the interphalangeal joints of the left thumb and middle finger

The accident occurred seven years ago, when she had had concussion following a fall from a trap She made a good recovery, but four years later noticed a tendency to painful swelling of the hands and feet, and, a year later, pain in the jaw The menses ceased two and a half years ago She had had severe frontal headaches since childhood, but these had been worse in the last 18 months She now had acromegalic facies, hands, and feet, with a chronic proliferative bone change in the proximal interphalangeal joint of the left middle finger and both joints of the left thumb, the terminal phalanges of all the digits were enlarged There was no optic atrophy, but a restricted field of vision in the upper temporal quadrant of the right eye The pituitary fossa was seen by radiography to be much enlarged and there was increased sugar-tolerance

Dr E STOLKIND questioned whether this were indeed a case of acromegaly there was no change in the tongue, which was the earliest symptom in 95 per cent of cases His view that there was no evidence for the traumatic origin was supported by Dr WEBER

Ulceration of Lip in Leukæmia

Dr W A MILLIGAN shewed a woman of 47 with (?) tuberculous ulceration of the lip associated with lymphatic leukæmia There was a history of familial tuberculosis and of a sinus under the chin which had discharged for a long time In June of last year she had noticed a pimple on her lower lip which gradually formed an ulcer and spread to involve the whole surface of the lip It was very painful In addition she noticed enlarged glands in the axilla and groin The blood-count showed 96 6 per cent of small mononuclears.

The PRESIDENT said that it was very hard to say whether this lesion were tuberculous, and quoted a case of very acute and rapidly fatal ulceration of the anus and another of severe Vincent's angina in leukæmia

Dr WEBER said that very severe inflammation was well known in acute leukæmia but this case was chronic If it were tuberculous it would probably have blocked the lymphatics and produced a septic elephantiasis—Dr H M ODDY, remarking that an air-cooled mercury-vapour lamp had improved the condition slightly, said that pressure was needed as well.—Dr L S T BURRELL said that he regarded the case as one of lowered resistance due to leukæmia, allowing the formation of a simple ulcer He had seen very bad oral conditions in lymphatic leukæmia A tuberculous lesion would have responded more quickly to treatment by light

Heart-block

Dr B T PARSONS-SMITH showed a man of 70 with complete heart-block

The patient had always smoked excessively, but had been a very moderate drinker and had had good health except for occasional bronchitis and one attack of pneumonia in 1918 Eighteen months ago he began to have frequent syncopal seizures with bradycardia The heart was found normal in size with a feeble apical impulse and sounds varying in intensity There was a soft systolic murmur at the apex The pulse was 30, the blood pressure 180/90 The presence of complete heart-block was confirmed by electrocardiographic and polygraphic tracings Since then the patient had gradually improved and resumed a quiet daily routine The syncopal attacks ceased after a course of adrenalin injections The block persisted, but caused no symptoms except occasional giddiness and sensation of heavy beating at night After a course of barium chloride (½ gr b d) the pulse-rate had increased to 40/50, and about two months ago rose to 72 with restoration of the normal rhythm. Just before Christmas the heart-block recurred but without symptoms This was ascribed to the barium, and suggested further inquiry into its dosage and combination with other drugs

Aleukæmic Lymphadenosis

Dr WEBER showed a Polish Hebrew tailor of 60 with symmetrical, general, moderate enlargement of all the superficial groups of lymphatic glands

The patient had had no previous illnesses and no symptoms There was no evidence of abnormalities in any viscera except some shadowing in the radiogram of the posterior mediastinum and hilus regions of the lungs The blood pressure was 145/95 There was no albumin or sugar in the urine The Wassermann and Meinicke reactions were negative and the Pirquet cuti-reaction positive The blood count showed 100 per cent hæmoglobin, 10,300 white cells, consisting of 49 4 per cent polymorphs (0 8 per cent young forms, 1 1 per cent with rod-shaped nuclei, 47 5 per cent with segmented nuclei) 21 4 per cent small lymphocytes, 21 per cent large lymphocytes, 1 2 per cent monocytes, 0 2 per cent basophils, 0 6 per cent. eosinophils, 3 2 per cent lymphoblasts, no myelocytes

Dr Weber gave this case the name of chronic lymphatic aleukæmic lymphadenosis because there was no great increase in the total white cells, but only a relative excess of lymphocytes. The generalised glandular enlargement and absence of blood-eosinophilia ruled out the diagnosis of Hodgkin's disease There might be a danger that active treatment by X rays would convert a chronic inactive case into an actively progressive one, he thought it was best left alone

Vascular Tumour of Meninges

Mr WAKELEY showed three cases The first had been shown in November as a tumour of the skull with definite evidence of a left-sided spastic hemiparesis with Jacksonian seizures Radiography revealed an area of rarefaction corresponding to the termination of the middle meningeal arteries At the operation the blood pressure had fallen to 80 mm. Hg when the osteoplastic flap was turned down, this should be an indication to stop any operation on the brain and the second stage was therefore postponed for ten days, when a large vascular tumour on the outer side of the dura mater and growing from a Pacchionian body was excised, substance whose physiology was largely unknown, but it was hoped that something definite would emerge from the present research

Dr S A KINNIER WILSON pointed out that epilepsy was not a disease entity but purely a symptom, recurrent fits accompanied many morbid processes such as cerebral tumour, neurosyphilis, arteriosclerosis, and many toxic and inflammatory conditions Epileptic symptoms were not themselves a sign of disease Convulsions could be brought about experimentally in animals which were anatomically and physiologically normal Many movements in fits were purposive in character, though they were outside volitional control There were cases in which not more than one or two fits occurred, and those fits therefore could not be looked on as manifestations of disease A fit was the discharge, the setting free, of accumulated nervous energy in healthy neuromechanisms Some fits were clearly cortical, some were caused at an obviously lower level, pontine or spinal, and he did not see why there should not be visceral fits The profession remained in ignorance, however, of the circumstances under which accumulated nervous energy was discharged, and this was the crux of the problem

Dr T GRAINGER STEWART said it was everyone's duty to try to help in the solution of this difficult question Probably all members in their practice saw cases which fell into certain groups, cases in which the association of the attack with certain physical changes was constant In seeking for the cause of epilepsy he thought it unwise to regard the disorder as a disease, it was a manifestation of something which was abnormal He advocated the collection and investigation of cases whose clinical features and physical changes were demonstrably similar During attacks some patients, for instance, developed sweat having a very pungent smell One case was that of a young woman, a teacher, who had been exposed to air-raids, which might be considered a psychical cause, she had never previously had epilepsy. Before a fit she had most offensive sweat, and after the attack had developed, instead of being fresh-complexioned, her skin became greasy, sallow, and blotchy, and was overspread with a layer of perspiration Her doctor said that previously her pulse had been normal All the cases he had had in this category recovered on being treated with belladonna None had had a recurrence during three years, and the longest time it was necessary to treat with belladonna was six weeks He held the view very definitely that not only one cause was at work in epilepsy, but there was an infinite variety of causes, acting in persons otherwise normal and healthy

Dr G. A. SUTHERLAND said that his difficulty had been in definitely recognising cases of true epilepsy He had under care a boy, aged 12, whom he first saw five years ago on account of petit mal, a diagnosis he had confirmed The boy had suddenly screamed and fallen unconscious, then was drowsy, and recovered He had had five such attacks but Dr. Sutherland now felt he had not had petit mal at all He thought that sufficient attention had not been devoted to the circulation in epileptic patients, though both Sir William Gowers and Sir Clifford Allbutt had said that there were no changes in the circulation Some attacks, he felt convinced, were due to cerebral anæmia In these the attack might be only mild, leading to syncope, or more severe, to the accompaniment of convulsive movements Another kind of attack was due to disturbances in the conducting tissues of the heart, and the change might take the form either of extreme tachycardia or severe bradycardia The attacks associated with heart-block were not due to a slowing of the heart beat, but to a standing-still of the ventricle for a few seconds These cases bore a close relation in manifestation to cases of epilepsy

Reply

Dr AIDREN TURNER, in reply, remarked that his chief submissions had not been seriously questioned With reference to Dr Sutherland's observations, in addition to arrest of ventricular action at the outset of a fit, a fall of blood pressure had also been noted Some authorities were inclined to attribute the convulsive seizure to arrest of cerebral circulation, but he was very sceptical as to that, and looked upon the arrest of the circulation as a consequence of the seizure He felt that little light had so far been thrown on the problem by the laboratory researches into the biochemistry of epilepsy, especially in France and America The charts shown by Dr Russell Brain were very interesting, but in some of the patients concerned there was a definite fall in the cholesterol content without any fit having followed And he felt a difficulty in regard to the attempt to harmonise experimental induction of convulsions in animals with what happened in the human epileptic patient The important point was whether in those animals anything like an attack of petit mal was produced, as that was the important manifestation of epilepsy, though admittedly grand mal was more spectacular

---

CLINICAL SECTION

EXHIBITION OF CASES AND SPECIMENS

A MEETING of this Section was held on Jan 14th, Sir HERBERT WATERHOUSE, the President, in the chair. A number of cases were shown

Thrombocytopenia Purpura Hæmorrhagica

Dr BERNARD MYERS showed a woman of 30 who had been seen by the Section several times before as a severe case of essential thrombocytopenia purpura hæmorrhagica She had started to bleed at the age of 12, but the first large hæmorrhage had been a menorrhagia at 24 All the usual means of treatment, such as calcium, sera, and blood transfusion had failed to effect more than a slight temporary improvement She had the typical reduction of blood-platelets, which were often absent altogether, the coagulation-time was normal, which differentiated her condition from hæmophilia, her bleeding-time was 15 minutes and the capillary resistance test was positive Splenectomy as recommended by the Section had now been performed, since when the patient's health had been excellent in every way and there had been no more hæmorrhages or purpuric spots The blood-platelets had returned to normal soon after the operation, and the bleeding time and capillary test were now normal Dr Myers remarked that there must be many cases of menorrhagia of this type going about unrecognised

The PRESIDENT, in answer to a question by Dr F PARKES WEBER, said that in the only fatal case of splenectomy he had known the patient had died of thrombosis in the splenic vein spreading to the superior mesenteric The operation might be extremely simple or very formidable, and it was difficult to forecast its result He regarded slipping ligatures as due to bad surgery

Case for Diagnosis

Dr SIBYL R EASTWOOD showed for diagnosis a case of left-sided muscular wasting of the type of Erb's palsy.

The patient was a boy of 16 who had been brought to hospital last August after a bicycle accident He had severe concussion and several bruises and abrasions, there was no fracture Four days later, when the symptoms of cerebral irritation had passed off, inability to abduct the left arm was noticed and had persisted Since then the shoulder had been kept abducted and massage and electrical treatment had been applied, but there had been no improvement except a very slight return of sensation

At the time of showing the boy held the shoulder on the affected side higher than the other, giving an appearance of some loss of substance in the left trapezius, but the muscle acted strongly and responded to faradism There was atrophy and paralysis of the left supraspinatus, infraspinatus, deltoid, biceps, coracobrachialis brachialis anticus, supinator longus, and clavicular portion of the pectoralis major muscles The slight relative weakness of other muscles was no more than might be accounted for by partial disuse There was diminished sensibility to touch, pain, heat, and cold

Reviews and Notices of Books.

HISTORY OF MEDICINE.

An Introduction to the History of Medicine from the time of the Pharoahs to the end of the Eighteenth Century By CHARLES GREENE CUMSTON M D, Lecturer on the History of Medicine and Medical Philosophy in the University of Geneva With an Essay on the Relation of History and Philosophy to Medicine by F G CROOKSHANK M D London. Kegan Paul, Trench Trubner 1926 Pp 390 16s

THE author of the ideal history of medicine would have to be one whose years were those of Methuselah whose knowledge of languages was equal to that of Mezzofanti and whose mental equipment was that of St Thomas Aquinas, Newton and Laplace combined Dr Cumston has attempted no more than an introduction to the subject, but in this introduction he has succeeded in laying foundations upon which those who care to go more deeply into the subject may build an elaborate edifice of knowledge In his first chapter he shows the importance of an understanding of the way in which our modern knowledge of health and disease grew like some great forest tree from very small beginnings, and all of us when we consider the discoveries and the mistakes of our ancestors, may well remember the dictum, "Do not despise the bridge which carries you across" Chapter II deals with Egyptian Medicine and Chapter III with Hindu Chaldean and Persian medicine, while in Chapter IV Dr Cumston discusses Homeric medicine and the views of the early Greek philosophers The next two chapters are concerned with Hippocrates and Hippocratic medicine various extracts from the Corpus being given which should certainly lure the reader to make further investigation into Hippocrates by way of the excellent translation now appearing in the Loeb library Incidentally, Dr Cumston would have done better to give his Hippocratic references more fully; he has given all his Homeric references in full, and a knowledge of Homer is far more widespread than is that of Hippocrates The direct successors of Hippocrates, the School of Alexandria, Erasistratus and Herophilus the Empirics and other schools and sects are described; Soranus is next mentioned, and the work of Caelius Aurelianus is very fully considered This writer, whose date is variously given as from the first to the fourth century A.D., is the author of a work upon acute and chronic diseases, which has come down to us in very bad Latin, but valuable in that it preserves many of the writings of his predecessors, he also made a not very accurate translation of Soranus Galen and the practice of medicine at Rome are discussed in Chapters XI and XII, and are followed by a chapter on Islamic medicine, which is perhaps the best in the book, although Dr Cumston might have made more of that great Nestorian school of medicine at Gondisapor whose researches were so valuable to the Arabs Chapters XIV, XV XVI deal with mediæval medicine including the schools of Montpellier and Salerno together with medicine and her handmaids in the sixteenth century, the three following chapters consider medicine in the seventeenth and eighteenth centuries Among the sixteenth century physicians Dr Cumston rightly gives much space to one who is too little known—namely Jean Fernel, 1497–1558 one of the earliest composers of a System of Medicine. Bichet is practically the last-mentioned physician and the book ends with a chapter upon the Evolution of Therapeutics

Dr Cumston's book is one which may be recommended, together with Dr Garrison's to all who wish to know something of the history of medicine

DISEASES OF THE HEART AND LUNGS

A Handbook for Nurses By A I G MCLAUGHLIN, M B, Ch M Syd Assistant Medical Officer Tuberculosis Dept, St Thomas's Hospital. London: Faber and Gwyer 1926 Pp 185 4s 6d

WITH the widening of the scope of their examinations nurses are finding that general text-books hardly cover the ground and the numerous small special system volumes which have been appearing recently are likely to be welcomed Dr. McLaughlin's book is a valuable addition to these He deals first with the anatomy and physiology of the heart and lungs and then discusses diseases of the heart and blood-vessels, and those of the respiratory system in detail, pneumonia and pulmonary tuberculosis being given separate chapters A section on surgical procedures contains a description of the principal minor and major operations on the chest, it is unfortunate that there is no mention of Burrell's aspirating apparatus since nurses often seem to find difficulty in understanding how it works There is an exceptionally good paragraph in which "heart attacks" are classified and described

SURGERY OF THE STOMACH

Chirurgie de l'Estomac Part I By HENRI HARTMANN With the collaboration of NICOLAE BARBILIAN, R BENSUADE CHABRUT-ASTAIX, DE POLIAKOFF, and ROBERT TARJAN Paris: Masson et Cie 1926 Pp 336 6s 8d

THIS is the first part of an extensive work on the surgery of the stomach, in which all aspects of the subject are treated in some detail The earlier part of the book describes the examinations necessary, including gastroscopy; for this the author predicts a great future, although he regards it as rather a dangerous method at present, only to be used when other methods of examination, apart from exploratory laparotomy, have failed to lead to a diagnosis A long section on the technique of operations on the stomach includes pre- and post-operative methods Here we find statistics collected about such rare operations as total gastrectomy and cardiectomy. The chapter on perforated ulcers of the stomach is particularly good Prof Hartmann rejects gastrectomy in these grave cases, believing that the mortality of this operation is twice as great as that of simple suture or suture combined with gastro-enterostomy a method which he believes gives results uniformly good All through the book cases are described which illustrate the points brought out and the whole forms extremely good reading The problems surrounding gastro-enterostomy are discussed in critical fashion We note that the mortality in the hands of Prof Hartmann and his associates has been 10 per cent in benign conditions, and the cause of this mortality is set forth in a section which is well worth perusal On the whole Prof Hartmann thinks gastro-enterostomy is an extremely satisfactory operation for ulcer wherever situated, for of 488 cases only 10 required a subsequent operation A clear account of gastro-jejunal ulcer and its treatment is included and an important section on cancer of the stomach where 100 cases are reviewed. The results of the excision of cancer have been particularly good

Altogether this book is a satisfactory achievement An enormous amount of literature has been examined and the subject has been treated from a judicial standpoint

ELEMENTS OF HYGIENE AND PUBLIC HEALTH

Second edition By CHARLES PORTER M D B Sc, M R C P Edin, Barrister-at-Law Medical Officer of Health Metropolitan Borough of St Marylebone London Oxford University Press 1926 Pp 425 14s

Dr Porter has the gift of writing in a bright and interesting way about subjects which do not lend themselves readily to such treatment The first edition of this book published in 1917, met the need for a work on public health more detailed than the elementary ones of which there is no lack but smaller and more readable than the tomes required by post-graduate students of hygiene and public health officials Both in its original and its newer form, Dr. Porter's book caters for medical students and also for practitioners who wish to familiarise themselves with public health practice Its revision is, however, only and bleeding was stopped by the diathermal cautery. The wound healed well and the patient was now able to walk, but still dragged his left leg.

Cirsoid Aneurysm

The second case was a cirsoid aneurysm of the right suprascapular artery in a man of 66 who first noticed a lump six months ago. The pulsating swelling lay below and slightly outside a congenital nævus and measured about 3 inches. Running down and slightly outwards from this was a dilated, tortuous thickened vein. There was marked pulsation and thrill and a diastolic bruit all over the swelling. These were eliminated by pressure on the subclavian artery, and removal after temporary ligature of this vessel was the treatment proposed.

The PRESIDENT and Mr. OGILVIE concurred as to the importance of temporary ligature, as the bleeding from this type of tumour might be appalling.

Paget's Disease with Nephrolithiasis

The third case was one of Paget's disease with renal calculus in a man of 67.

Enlargement of the head had been noticed six years and bowing of the legs four years ago. Twenty-six years ago some renal calculi had been removed from the left kidney and for ten years the patient had had periodical attacks of pain in the left loin. Last November he had a typical renal colic followed by swelling of the right testicle. Radiography showed four large stones in the left kidney and cystoscopy revealed a cystitis and a little pus exuding from the left ureter. The urea concentration of the right kidney was 2·74 per cent., so nephrectomy was performed. Owing to the kyphosis the last rib almost met the iliac crest, and made the operation difficult, but recovery was uneventful.

In reply to a question Mr. WAKELEY said that he did not mean to suggest any connexion between the two conditions, but Dr. E. I. SPRIGGS remarked that recently an attempt had been made to ascribe all these conditions to an infective origin, and quoted a case of a patient under his care in whom the bone disease had distinctly improved after the removal of a chronically inflamed appendix.

Mr. OGILVIE showed a case of

Tumour of the Calf

At the age of 19 (40 years ago) the man had twisted his right leg and been three months in hospital; there had been no fracture. During the next 12 months a lump slowly appeared in the left calf and since then had given no trouble. The swelling was large, rounded, placed deeply in the gastrocnemius, elastic but not fluctuating, and not tender. It was probably a thick-walled cyst of traumatic origin. Mr. Ogilvie compared it with the cysts due to rupture of the rectus in typhoid, and pointed out that it must be a real tumour, as inflammatory fibrosis would have diminished in size after all that time.

The CHAIRMAN remarked on the size of the lesion and said he had a strong suspicion that these lesions were all really sarcomata. Cysts about the knee were liable to travel down the calf, and this might be an example.

Mr. OGILVIE agreed that it might be in the nature of a Baker's cyst.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH

AT a meeting of this Institute held on Dec. 21st last Major WALTER ELLIOT gave an address on

CLINICAL RESEARCH IN ITS RELATION TO THE PUBLIC HEALTH SERVICES

Expressing his conviction of the valuable results which must accrue from the meeting of public health administration and general practitioners he laid it down as a fundamental rule that every respect must be paid to the opinions of those in touch with the living being. The fact that for the first time in history research had figured in the agenda of the Imperial Conference which had been held during the autumn marked a distinct stage in the attitude of our administration to it. But there was a danger that too much reliance was being placed upon the word "research" and that anyone getting into difficulties had only to pronounce the magic word to have these difficulties overcome. There was also the danger of clinical research coming to be looked upon as something apart from the practice of medicine, whereas it should grow out of the daily work of practitioners. It required observation, intuition and imagination, just as much in the clinician in his daily round as in the laboratory worker.

In the relationship of clinical research to the public health services there was the danger that the enormous machine of administration might prove of more injury than service to the work of people who were, so to speak, on their own and uncoördinated. One way to avoid this danger was to imbue the minds of the administrator and the clinician with a proper conception of the work and difficulties of research. The administrative worker must come in contact with the growing process which research represented.

The sum of £2,860,000, said Major Elliot, had been spent in Scotland on feeding at the public expense during 1926, and the State had been devoting particular attention to the problems of nutrition as affecting child welfare, particularly with regard to rickets. Public authorities were beginning to spend large sums on irradiation. Expenditure on treatment by cod-liver oil, however, might be counted in pence against shillings for treatment by light, and authoritative scientific opinion might thus be of immediate financial importance. The problem was fully discussed in the Scottish Board of Health Report for 1925 and a Conference had been called in Edinburgh in July, 1926, by the Board of Health with the object of enlisting the physiologist and biochemist to serve the clinical man who had for many years worked at the problem. The idea was to give the clinician the actual living work of the scientist and not the published results alone. This was an attempt to yoke the science and art of medicine together to this practical problem in Scotland and it was an example only. The general questions involved were of great interest and importance.

The relationship of research and administration had been considered at the Imperial Conference, and Lord Balfour had made a preliminary survey of the problem, which though it dealt with industry and agriculture rather than medicine, was largely applicable to the question under discussion.

"Can we suppose," said Lord Balfour, "that either money or organisation can increase the supply of original scientific genius, or direct it, when found, into utilitarian channels? It is plainly impossible. Genius cannot be made to order nor discovered by rule. The best we can do is to provide fitting opportunities for its exercise when we are fortunate enough to find it. Yet I am convinced that much may be accomplished if we are not too ambitious. How, then, is it possible for the Conference to assist? It cannot give money; it cannot impose a policy. Let us cultivate easy intercourse and full coöperation. Investigators in the same intellectual field, though far separated in space, will work as partners. Overlapping, and all the intellectual waste that accompanies overlapping, will be greatly diminished; and considered judgments about the gaps in our knowledge which most urgently require to be filled will follow as of course."

In conclusion Major Elliot said that public health work would increasingly concern itself with research; that control, especially superimposed control, would of necessity fail, and opportunities for work were the most that organisations could hope to offer; and that the independence of scientific institutions ought to be jealously guarded so as to provide the necessary check on the rapidly increasing undertakings of State research.

THE LANCET.

DON: SATURDAY, JANUARY 22, 1927.

HEALTH INSURANCE FUNDS [1]

second valuation of the assets and liabilities ieties approved under the National Health nce Acts has given the Government Actuary portunity of setting out the financial basis of alth insurance scheme which granted certain ons to be mentioned later, is one of undoubted h. The audit itself has been laborious enough re are more than 8000 societies (reckoning the ies of large societies as separate units) com- some 15 million members, and the valuation ken account of the sex, employment, present nd probability of survival of each of these ers, as well as of the fact that the amount of ss increases among them (from one week at the to 15 weeks in the year at the highest) as age ses, while the number of persons entitled to t as regularly diminishes Such a valuation, gh based on experience of the past, relates future, and involves the recognition and con- tion of all the risks and changes which the may bring The capital credits of all these es at the valuation date (the last day of 1922 e smaller societies, of 1923 for the larger) ited to nearly £190 million, of which £5 8 has been allotted to contingencies and £2 4 to administration The total surplus at me date was £42 4 million, being an average of £2 16s. 8d a member Not that all the es were in the happy position of making a on their labours, for 134 of them, comprising 0 members, showed an average deficiency of ember—it is one of the demerits of the present that certain groups of insured persons through lt of their own obtain less benefits than do , although, of course, no member is deprived minimum benefit guaranteed to him under cts The existence of a profit of well over illion on the working of the health insurance during the first 11 years of its existence is g evidence of the acumen of those who drafted nd secondarily, of the remarkably high level od health among employed workers The sh group of societies shows up the best in this t, Scottish, Northern Irish and Welsh following scending order As has long been surmised, it insured men who bring profit into the scheme, uring the inter-valuation period the cost of ess and disablement benefits yielded an average on the estimates of £1 7s 6d a head in the of men and of barely 6s a head in the case of en, while a group such as the Industrial Assur- and Collecting Societies, containing 43 per cent omen members, has a small disposable surplus ared with the Trades-Union group, containing 19 per cent of women workers—only about alf in fact

is not the intention of the Commissioners to bute the whole of this enormous surplus during the next five years Sir ALFRED WATSON is a cautious person and foresees the unlikelihood of so large a balance being available five years hence, and he counsels not to give more additional benefits than there is reasonable expectation of maintaining The total distributable sum is therefore fixed at £27 million, in which 97 per cent of the total members are entitled to participate of this sum £18 3 million will be absorbed by additions to the statutory money benefits, leaving £8 8 million for additional benefits in *other forms* or approximately 3s 7d per insured person per year In the case of more than one-half of the total insured population the surplus available for distribution is sufficient to provide additional sickness benefit of 5s a week (it is now 15s for men and 12s. for women) with corresponding increase in disablement and maternity benefits leaving 5s 7d. a year for other forms of benefit Disablement benefit has been making large inroads on the fund during the inter-valuation period, while the claims of men rose from 42 to 74 per cent of expectation, it increased in the case of women from 81 to 146, the excess in the claims of women being the explanation of the inferior position shown by women's societies in the valuation The financial basis is now to be altered in accordance with this experience so as to provide for an expenditure on sickness and disablement in the case of women at a rate 60 per cent greater than on the basis for men Although there is no occupational classification of insured persons certain types of occupation (strongly represented in certain societies) have been shown to carry heavy sickness rates but the valuer explains that it is in the more arduous occupations that capacity for work has to be measured by more exacting standards of physical fitness The valuation also throws some light on the relation of child-bearing to employment, for the birth-rate among married women who are industrially employed is seen to be little more than one-half of that among the whole class of married women The figures also prove an average unemployment during the three years 1921–23 of 16 per cent of the whole membership These are some of the facts which will interest medical men and should induce them to read as a whole a report which so clearly exposes a complex financial scheme

SIR ALFRED WATSON concludes that there is a reasonable expectation of the continuance of additional benefits, provided that certain conditions are fulfilled . first. that a high standard of administration by the approved societies is maintained, secondly, that the full coöperation of the medical profession in regard to the certification of claims is ensured; and, thirdly that such unfavourable visitations as that which has been encountered in the present year prove to be transient Obviously two of these factors are not within the competence of the medical profession to arrange In regard to the certification of claims, there is the paradox that during the recent period of industrial strife, although there was no manifest increase of general sickness, there was a huge relative increase in sickness benefit, some societies paying three, four, or even five times as much in the 1926 period as in the corresponding period of 1925 That is a problem which did not begin in May, 1926, nor did it end with the resolution of the mining dispute The experience of the old friendly societies was that every period of temporary distress in the economic world meant an increase of sickness claims Unemployment insurance, poor relief, and child welfare expenditure all showed simultaneous increase, and it is obvious that greater partially successful The changing aspects of hygienic teaching can hardly be reflected in the later editions of any such work without drastic rearrangement of its contents For instance, it cannot be said that present-day ideas as to ventilation, or the significance of accessory food factors and the balance of amino-acids in proteins find adequate expression in the chapters dealing with these subjects, and it is disappointing that the description of various means of disinfection is not accompanied by any discussion of the value or importance of disinfection as usually practised Again, it would have been worth while, in our opinion, to devote a little space to a judicial consideration of the extent to which domestic refuse is, or is not a real danger to health The treatment of special schools is, to say the least of it, perfunctory We notice, too, the retention of the old family names for the varieties of rats There are also some minor inaccuracies It is not strictly correct to say that Orders of the Ministry of Health are merely instructions to local authorities, or that the heat obtained from electric fires is almost entirely radiant, or that payment of emergency fees under the Midwives Acts by local authorities is optional These criticisms are made in no captious spirit, but since we believe that public health policy must depend to a great extent on the enlightened views of practitioners, to whom the public look for guidance on matters affecting both their own health and that of the community, we feel that space devoted to descriptions, diagrams, and illustrations of drains, traps, and sanitary conveniences might well be sacrificed to the discussion of the fundamental problems of hygiene The general ground of public health, however, is well covered in this book, and it can be confidently recommended to students who wish to provide themselves with a text-book which will be useful for reference when they enter the general practice of medicine.

THE ENDOCRINE ORGANS

Part II. Second edition By Sir E SHARPEY-SCHAFER, LL D , D Sc , M D , F R S , Professor of Physiology in Edinburgh University. London Longmans, Green and Co , Ltd 1926. Pp 118

SINCE the new edition of The Endocrine Organs (Part I) was published in 1921, this supplementary volume has been eagerly anticipated Prof Sharpey-Schafer is probably better qualified than is any other man to speak with authority upon this subject, and in these publications he not only collects the extensive literature dealing with endocrine physiology, but he edits it with a critical eye

This volume, which fully maintains the high standard of its predecessor, deals with the pituitary, pineal, alimentary canal, pancreas and sex glands There is also included a small supplement to Part I , giving details of recent advances made in our knowledge of the thyroid, parathyroid, and suprarenal capsules For example, the question of the differentiation of exophthalmic goitre and toxic adenomatous goitre is discussed, and the value of iodine in the treatment of the former mentioned Reference is also made to the experiments of Collip with parathyroid extract Prof Sharpey-Schafer points out that this work has placed beyond doubt the question of the activity of this extract in regulating calcium metabolism and especially the percentage of calcium in the blood In the main part of the book much space is devoted to the pituitary body The early chapters deal with the morphology and general and microscopic structure of the gland, which is described as being made up of four parts, the anterior, tuberalis, intermedia, and nervosa Particular attention is directed to the pars tuberalis and pars intermedia Ten chapters are allotted to the action of extracts of the posterior lobe on the various systems of the body, and others are concerned with the clinical syndromes associated with pituitary disease and with the relation of this gland to the other endocrine organs Finally, the therapeutic uses of pituitary extracts are discussed Many of the problems which arise in connexion with pituitary function must be considered as still undecided, and where this is so Prof Sharpey Schafer gives a full critical review of the reliable evidence Moreover, his criticism is always constructive A good example of his method of dealing with controversial questions occurs in his presentation of the problem of polyuria and the pituitary body He points out that while some clinicians and experimental workers regard the polyuria which accompanies tumours of the pituitary region as due to an effect upon the pituitary itself, others consider that it is the result of pressure on the base of the brain, the tuber cinereum The evidence for these views is completely discussed , the author considers that insufficient account has been taken of the pars tuberalis of the pituitary, which is intimately connected with the tuber cinereum, over which it spreads for some little distance, and his personal bias appears to be in favour of an effect on the gland itself The remaining third of the volume deals with the pineal body, pancreas, and sex glands , a very full account is given of each The method of incorporating in the text full references to recent experimental work adds much to its value In the section devoted to the ovary there is no mention of the work of Allen and Doisy in the preparation of ovarian extracts

Clinicians as well as research workers will appreciate this treatise

JOURNALS

INDIAN JOURNAL OF MEDICAL RESEARCH Vol XIV No 2 —Of the 21 contributions to this number it is possible to select some papers of more than ordinary interest L E Napier is now able to present an analysis of the first 104 cases of kala-azar treated with stibosan (von Heyden 471) The mean dose of this drug required for a cure is 4 0 g , individual injections of 0 3 g appear to be well tolerated —Prof F M Marras of Port Said, describes a rapid method for the diagnosis of plague By adding a small quantity of agglutinating anti-plague serum to a solution of sugars, such as lævulose, glucose and mannite, he obtained a marked acceleration of the fermentation and could ascertain at the same time the specificity of the bacillus by microscopic agglutination —Major-General T H Symons, I M S , describes an epidemic of Tick fever due to *Piroplasma gibsoni* amongst a kennel of foxhounds belonging to the Madras hunt. The actual tick-vector has not been incriminated Whilst intravenous salvarsan is a fairly efficient remedy, the recently introduced tryparsamide seems to be superior —H E Shortt, P T Barraud, and A C Craighead contribute a detailed article on a massive infection of the buccal cavity of *Phlebotomus argentipes* with *Herpetomonas donovani* artificially fed In a separate contribution the same authors record the capture in a heavily infected kala-azar house of a naturally infected specimen of this sandfly The significance of the findings is obvious and points to the assumption that the monsoon period is one during which infection with the parasite of kala-azar may be acquired and that the sandfly is the transmitting agent —R McCarrison writes upon Lathyrism in the Gilgit Agency, in which he describes an outbreak of this curious disease due to the ingestion of millet grown on soil which had received no manurial treatment for many years —Asa C Chandler and V T Koike contribute papers of helminthological interest

A HOSPITAL ON WHEELS —Dr H Bailey, medical officer of health for Horsforth, in the West Riding, suggests the possibility of utilising a portable hospital on wheels or otherwise for the use of single patients in outlying districts where the house accommodation is unsuitable or where it is found impossible to remove the patient safely "A caravan," Dr Bailey says, "having ample accommodation for nurse and patient would prove a great boon, and could be got ready with little more trouble than that required for the preparation of a fire-brigade engine " medical opinion in regard to it ever since, "epilepsy" is at once much too manifold to be a single "disease" and too restricted for the purposes of the clinician. It is an ailment, in the sense of the German equivalent "Sucht" but in no sense of the term can it be regarded as a nosological entity complete in itself No one was more aware of the handicap imposed on research by terminological obstacles of this kind than HUGHLINGS JACKSON, who was wont to speak of "the epilepsies," *thereby to indicate the semiological rather than the* pathological meaning of the word. In truth, epilepsy is no more than a descriptive term for one symptom of a general class of symptoms brought about by a variety of pathological states, and when in the Registrar-General's Reports we find it put down as responsible *annually for a large* number of deaths on the same level precisely as cerebral tumour or pneumonia, we can realise the urgent need of revision of current opinions and the mountain of prejudice which will have to be moved if modern knowledge is ever to prevail

To envisage the problem in its appropriate setting, we have to begin with the proposition that a fit is a *transient disturbance of neural* function, possessing as a rule the features of suddenness or abruptness, disorderliness, and severity, it may or may not be accompanied with loss of consciousness, be preceded by an aura or warning, and followed by a period of exhaustion Fits may, or may not, recur In respect of each one of these components so much symptomatological latitude is possible that comprehensive definition can scarcely be reached *Examined* physiologically, a fit represents the setting into motion, or the release from control of a quantity of potential, static, neural energy, housed in neurones so linked with each other that once the process is started it may spread both laterally, on a given level, and downward to levels of a *lower* physiological grade Moreover, theoretically any group of *neurones*, at any level, may form the site of the initial excitation or release, hence clinical variants are numerous Careful observation of the phenomena during the *brief period* of their existence makes it clear *in some* instances that pontine, bulbar, and possibly spinal mechanisms are involved, in others, *units of the* rolandic motor area are the first to exhibit activity, in still others, the type of movement strongly suggests irritation or decontrol of cortical areas of considerably higher physiological grade If, *for the sake of* harmony, we can conceive of psychical energy as being but a form of physical energy, if, *adopting the* principle of emergence, we can believe that consciousness and reflective thought arise from the *complex* functioning of neurones, and do not constitute an activity of another order than the neural—then we can bring into line with the above mentioned physiological processes of the fit those cases, and they *are many*, in which symptoms belonging to the psychical series are in evidence For the aura of the fit is in all instances a conscious sensation and, therefore, a psychical thing, yet it is no less integral an accompaniment of the fit (should it as a fact be present) than the subsequent unconsciousness or the *motor* display Of it, too, we might then conceive as being a phenomenon of release or of excitation, and we should not have any *difficulty* in unifying the multiplex semiology of epilepsy, *from* aura to cyanosis, from finger-twitching to vesical evacuation, as standing only for differences in degree, range, and site, of one and the same kind of dysfunction Contrasts between hysterical and epileptic seizures would lose their force and point, and this would be an unalloyed gain to the scientific neurologist, though, naturally, prevailing clinical distinctions would not thereby be obliterated Finally, in this connexion, it would not be arduous to correlate the manifestations of petit mal with those of the major variety, *for they would* represent a minor degree of disorder of function of neurones subserving consciousness, without, or with a minimal, spread to those whose activities are motor. Thus, too fits without *actual convulsion* would be better understood

Another proposition well worth bearing in mind is to the effect that epileptic symptoms are the outcome of the *activation of normal, healthy neural* mechanism, and can in no sense be prima facie evidence of the existence of disease The arguments in favour of this view need scarcely be summarised A moment's thought will show that complete functional restitution after a fit eliminates all question of structural defect Convulsants of the absinthe and thujone class produce fits in perfectly normal laboratory animals Clinical data might be adduced in abundance to support the contention Wherein, then, does the abnormal element consist? The key to this particular aspect of the problem is to be sought in a survey of the conditions as a sequel to the presence or recurrence of which neural energy is allowed uncontrolled liberation and rapidly passes along and down neuronic lines (and up, too, if certain data which *cannot here* be examined are accepted) Ignorant as we are of the normal processes of volitional *innervation*, *we are* quite at a loss when an attempt is made to visualise or conceive otherwise of the exact mechanism of de-inhibition But some help is forthcoming from a consideration of the *organic conditions apt* to be associated with the appearance of epileptic symptoms Fits are prone to develop with locally altered vascular conditions (as in cerebral embolism, thrombosis, hæmorrhage), with more general states of intracranial pressure (in cerebral tumours), or of a toxic *character* (*uræmia*, eclampsia, artificial convulsants) For the vast group of epilepsy of unknown origin we must by analogy postulate the existence of a factor, or, more probably, of factors which are capable of exercising the same effect on nerve-cell constellations as do the mechanical, vascular, or toxic factors just *mentioned* That they may on occasion be constituted by some, as yet, ill-recognised biochemical *change* is far from improbable, but not inherently more feasible than that in other instances stimuli of a psychical order should suffice equally well to cause a similar energisation, or, rather, a setting free *of energy* existing in potentia Approach to the perplexities offered by epilepsy is, therefore, welcome from any side, chemical or mental, vascular or neural But none can ever be acceptable which ignores the complexity of the subject, fails to embrace the multiplicity of clinical variants, or does not keep *steadily* in view the problem as a whole

---

MEMBERS of the profession will be glad to learn that a presentation is to be made to Sir Berkeley Moynihan on his retirement from the active staff of the University and General Infirmary at Leeds Sir Berkeley Moynihan is the first surgeon from the provinces to be elected President of the Royal College of Surgeons of England, and the work which led to his election is known all over the world and has added distinction to British surgery A committee has been formed, of which the Lord Mayor of Leeds is chairman and Mr L R Braithwaite *vice-chairman*, and its intention is to collect subscriptions *for a portrait* of Sir Berkeley Moynihan to be placed *in the* board room of the General Infirmary Whilst the smallest contribution will be welcome, it is suggested that no *individual* amount should exceed £5 stringency in certification would afford no complete protection to health insurance funds The insured population will have to learn that they are contributing to a fund of their own for certain definite and desirable purposes that this fund is not unlimited, and that the more they ask for trivial complaints the less likely becomes any extension of the scheme to include specialist and hospital treatment The last seven months have been indeed a searching time for the principle of contributory insurance as a method of financing medical service, and for the health of the coming generations it may be that schemes of additional benefit will have to be put on a less uncertain footing than the amount of surplus accruing at five-yearly valuations

◆

SOME PROBLEMS OF IMMUNITY IN TUBERCULOSIS.

THE scientific beliefs of one generation are frequently anathema to the next In a paper read at the recent Tuberculosis Week end Conference[1] in London and published in our present issue, Dr GEORG SCHRODER, one of the most experienced of sanatorium directors, discusses some of the problems of immunity in tuberculosis, which appear to be not much nearer solution now than they were a generation since Thirty-five years ago ROBERT KOCH introduced his "lymph," which soon came to be known as tuberculin, and opinion is still sharply divided as to its therapeutic value and its mode of action It might be difficult to determine the extent of its use at the present time as compared with, say, 20 years ago, but judging from the number of original papers written and published on the subject there is no sign of complete disbelief in its efficacy, though there is a vast deal of healthy agnosticism Dr SCHRODER would presumably include tuberculin amongst the other so called specifics which cannot be "absolutely relied upon for treatment or for prophylaxis" Probably few clinicians—and still fewer immunologists—nowadays could be found to subscribe to the original view of KOCH's day that tuberculin is a true antigen in EHRLICH's meaning of the word, generating a specific antibody to tuberculosis It is some years since A WOLFF-EISNER suggested that, in clinical tuberculosis, there is an increased sensitiveness not only to tuberculin but also to protein-split products in general, and the tuberculin reaction seems now to be generally accepted as not specific in the narrow acceptation of that word Dr SCHRODER goes further in suggesting that tuberculin, by acting as an irritant of tuberculous tissue, promotes the "natural disintegration of the focus of disease" A similar view has been advanced in various quarters as an explanation of the action of sanocrysin and other chemotherapeutic remedies If this view be correct the question naturally arises, What relation has this disintegrating action to the formation of connective tissue in a chronic tuberculous focus? Dr SCHRODER attempts an answer with the explanation that the collateral zone of inflammation is protective, and that when the stimuli are not too strong connective tissue is formed, as a result of stimulus, in the reticulo-endothelial tissues surrounding the avascular tubercle This theory is not new, but it is a sign of the times that it should be advanced now in so many quarters as a modification of the pure and unadulterated doctrine of tuberculin specificity on which scientists staked their reputation a generation ago

If it be assumed—and it is a large assumption—that a tuberculous focus needs a stimulus to disintegrate the tuberculous tissue and promote fibrous tissue formation, does it necessarily follow that tuberculin—or for that matter any other foreign protein or chemotherapeutic remedy—can supply that stimulus in a way which the tubercle bacillus itself cannot? The available evidence is all too vague for a categoric reply Indeed, the whole question is a good example of the loose way in which the word specific is often used both by sanocrysin and by tuberculin advocates In the case of tuberculin attention has, for the moment, been directed to the possibility of standardising the product on immunological lines The questionnaire recently issued by the Health Section of the League of Nations has elicited much interesting information and has stimulated research, but it has revealed no consensus of opinion There are at least four methods of standardisation in use, giving different results, and until the immunologist can get down to a basic standard the clinical records of tuberculin are really not comparable one with the other A further pertinent question dealt with by Dr SCHRODER is that of allergy He makes the point that "the stronger the allergy the greater the resistance," in other words, allergic behaviour and resistance to infection run, to a certain extent, on parallel lines C v PIRQUET also has pointed out that in measles the positive allergic reaction to tuberculosis, which he, too, regards as protective, may be abolished If this be so, it would afford support to the clinical finding that an attack of measles increases the susceptibility to tuberculosis A further instance of diminished allergy is quoted in the cases of tuberculous meningitis observed in HAMBURGER's clinic Dr SCHRODER deduces that cases showing high allergic response are likely to do well without specific therapy, whereas those with a low allergic reaction may be helped by such treatment Unfortunately, allergy is itself an ill defined conception in clinical practice, and attempts to measure allergic response by laboratory means have not been very successful Dr SCHRODER mentions numerous tests which have been used, from the older graduated Pirquet reaction to the newer sedimentation test Some of them are probably more sensitive and illuminating than the general run of temperature charts, but they are often no more specific than is pyrexia and until a sufficiently large series of quasi-continuous observations can be made on individual patients their practical utility as a means of gauging resistance or allergic response must be limited

◆

A DISCUSSION ON EPILEPSY

ON another page will be found a report of the discussion on epilepsy, which occupied the Section of Neurology of the Royal Society of Medicine last week A short time ago we summarised the presidential address of Dr ALDREN TURNER, on the same subject, delivered before the Section of Psychiatry of the Society It may accordingly be convenient to take this opportunity of reviewing some of the questions presented by a perplexing malady, still surrounded by obscurities that, in view of its history and of its frequency, constitute no little reproach to medical science and art By way of preface, it is only right to point out that epilepsy occupies a peculiar if not unique position among morbid states, and suffers from the paradoxical disadvantage of being an age old "disease" Known from the earliest times as "the falling sickness," a conception which has coloured recovered from the disease. The donor must have a negative Wasserman reaction and be entirely free from all acute symptoms such as fever, myoclonias, diplopia, respiratory catarrh. With strict aseptic and antiseptic precautions, 30 c.cm. of blood are withdrawn by means of a syringe every three or four days from the donor; the blood is then transferred to a centrifuge tube and the serum allowed to separate by standing or centrifugalisation. The supernatant serum, which should be perfectly clear, is next transferred into ampoules for 6 c.cm. doses. Controls are made with bouillon cultures and any ampoule showing cloudiness or serum on the surface is discarded. The serum will keep in ampoules in the ice-box for a period of six months. The treatment is performed every three or four days and repeated according to the indications presented by the patient. After withdrawing 10 to 30 c.cm. of cerebro-spinal fluid, 6 c.cm. of the serum is injected intraspinally. Immediately after the intraspinal injection the foot of the bed is raised one foot high, in order to avoid a too sudden and abrupt diminution of the intra-cranial pressure. Adrenalin chloride (1 in 1000) 0.5 c.cm. is injected hypodermically to minimise the risk of anaphylactic shock. A few hours after the injection rise of temperature occurs to 38°-39° C., with lumbar pain, headache, and hyperæsthesia along the lower extremities, the symptoms lasting for three to four days. Dr. Sison also tried inoculation with benign tertian malaria, but not in a sufficient number of cases to warrant any conclusion. No improvement from any therapeutic measure was observed in patients suffering from the Parkinsonian syndrome.

---

[1] THE LANCET, 1926, ii, 1134

SUMMER DIARRHŒA—A PREVISION.

UNTIL a few years ago it was taken for granted that all diarrhœa in the summer-time was the direct result of an infection and could be prevented by cleanliness alone. Very obviously the proportion of true infective diarrhœa varies with the climate of the country and with its advance in the science of public health. We read with interest in American and Australian journals of blood and mucus being ordinarily found in the stools of infants with diarrhœa, whereas these manifestations are very rare in this country. Summer diarrhœa is not the cause of high infant mortality in Scotland—probably because of the climate—and it is well, therefore, to realise that the problem varies in different places. There appears to be very little ground for assuming that an infection plays a primary part in the vast majority of these cases in the British Isles, possibly not more than 1 in 10 is infected with the true pathogenic organism. The clinical picture in such a case is clear-cut, with its profuse blood-stained mucous stools and high temperature. All efforts at aborting such a case by the usual means fail utterly, and it runs its full course, just as typhoid does, regardless of any known treatment. Of the remaining 90 per cent., a few are symptomatic diarrhœa—that is, general infections to which the child reacts by profuse diarrhœa. These cases are seen throughout the year with middle-ear disease, pyelitis, or during influenzal epidemics, but represent a very small proportion only. Marriot[1] has recently pointed out a most interesting group of cases suffering from acute diarrhœa which fail to react to any treatment, waste rapidly, and have a continuous high temperature. Only the most careful examination reveals a subacute infection of the mastoid bone on one or both sides, and operative treatment seems to be indicated. The incidence of otitis media and mastoid disease in this country is much less than in America, and this complication is probably an extreme rarity here.

The vast majority of cases of so-called summer diarrhœa are purely dietetic in origin—that is, they are preventable. The children who suffer from this disorder, as Dr. Ronald Carter points out in a paper which we publish on p. 176, fall into two main groups: (1) perfectly healthy children, and (2) those who have been chronically ill. In the infant up to, or over the normal weight, an acute bilious attack very often occurs because of overfeeding, especially on fats. Infants fed on full-cream mixtures, or breast-fed babies not given sufficient water for their needs in warm weather, make up the majority of such cases, and their treatment in summer is just what it would be at any other time of the year—a purge, starvation, except for the addition of a little sugar, and gradual resumption of diet. Such cases are seen in the well-to-do, but are so promptly dealt with that the mortality remains negligible. Among the ignorant, however, it is often several days before advice is sought, and meanwhile attempts have been made to continue with the ordinary diet, so that a fatal issue is *common*. The other group is formed by those children who have been chronically underweight, or have failed to gain in weight; they have had slight recurring attacks of undigested or acid stools, even before the warm weather, and they may be termed the chronic indigestion group. The average infant requires less food—that is, a smaller caloric intake—during the summer months than in the winter. This is especially true if it is overclad or confined in a warm still atmosphere, such as is found in the poorer districts of great cities. The digestive tract, which has been struggling to cope with and metabolise sufficient food for the infant's requirements during the winter months, becomes hopelessly overloaded unless the supply of food be curtailed during the summer. Recent work on gastric acidity[2] in infancy has shown that the infant which, for any reason whatever, is below the normal standard of health, tends to have a decrease in its gastric function, and it is reasonable to presume that there is a similar decrease throughout the whole intestinal tract. It can be readily seen, therefore, how overfeeding in an infant with chronic indigestion during the summer months produces a sudden catastrophe. When we turn to the prevention of summer diarrhœa we must obviously concentrate on the feeding and care of the infant. To those familiar with the problem there seems little doubt that the welfare movement has contributed by far the most towards the present enormous reduction of diarrhœa, and, therefore, of infant mortality. The education of the mother in all branches of mothercraft is all-important. It should be asked, however, where the welfare movement fails in respect of summer diarrhœa, or, to put it in another way, how could the situation in summer-time be coped with at the welfare centres? Generally these centres are open for consultations only once or twice in the week, and it is in the intervals between visits that calamities occur. Some few centres even close their doors during the summer months because of reduced attendance on the part of the mothers, whereas actually they should arrange to sit daily during the months of July, August, and September. If the situation be grasped and the mother advised promptly, even in the frail subnormal infants gross intolerance to food may be prevented.

Having made certain that continuous expert advice is available for every well baby, it must be considered what advice is to be given. The mother should be told the advantages of keeping her infant lightly clad and cool throughout the day; she should be told that her child needs frequent drinks of water at regular intervals throughout the day and night, quantities equal to at least half the total of its feeds being offered throughout the warm months, and she should be warned against any attempt to urge food on the baby. In April, May, and June an effort to raise the child's tolerance for sunshine should be made, and it should be exposed to the direct rays of the sun before their strength becomes too great. It is notorious that the sunburnt babies rarely develop summer diarrhœa. In the hot, close days of the year the mother must transport her infant to the open spaces for part of the day. Heat alone is not as much to be feared as still, devitalised air. Those children on full-cream, dried, or fresh milk mixtures should be

Annotations.

"Ne quid nimis"

VITAL STATISTICS FOR 1926

THE Registrar-General has issued a provisional statement of the figures for birth-rate, death-rate, and infantile mortality during the year 1926.

—	Birth-rate	Death-rate	Infant mortality-rate.
England and Wales	17.8	11.6	70
105 county boroughs and great towns including London	18.2	11.6	73
158 smaller towns	17.6	10.6	67
London	17.1	11.6	64

The smaller towns are those with an estimated population in 1921 of 20,000–50,000. The (crude) death-rate for England and Wales relates to the whole population, but that for London and the two groups of towns to the civil population only. Birth-rate and death-rate are per 1000 population, infant mortality-rate per 1000 births.

The Registrar-General remarks that the birth-rate is 0.5 per 1000 below that of 1925, and that, with the exception of the rate in 1918 (the last year of the war), it is the lowest recorded. The death-rate is 0.6 per 1000 below that recorded in the previous year and is equal to that of 1923, the lowest recorded rate. The infantile mortality-rate is 5 per 1000 births below that of 1925, but 1 per 1000 above that of 1923, the lowest on record. These provisional figures, which are not likely to require substantial modification, have been issued for the information of medical officers of health.

THE FIRST WEEK OF 1927

THE Registrar-General's return for the first week of the present year has just been issued, and we take the opportunity of calling the attention of the medical profession as a whole to a document whose careful study will keep the practitioner informed of the prevalence and spread of infectious disease throughout England and Wales.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 412 (previous week 342); scarlet fever, 1468; diphtheria, 1179; enteric fever, 37; pneumonia, 2033; puerperal fever, 54; puerperal pyrexia, 139; cerebro-spinal fever, 7; acute poliomyelitis, 24; acute polio-encephalitis, 3; encephalitis lethargica, 39; dysentery, 6; ophthalmia neonatorum, 112.

The cases of small-pox were reported from the following counties: Durham, 284 (11 from Gateshead, the remainder from 22 urban and rural districts, the highest figures being Chester-le Street R.D. 40, Crook 32, Brandon and Byshottles 30, Lanchester 27, Hetton 22, Willington 21, Shildon 19, Jarrow 14, Easington 12, and Tanfield 10); Lancaster, 1 (Ashton-under-Lyne); Lincoln-Lindsey, 7 (Gainsborough); Northumberland, 5 (Newcastle 1, Tynemouth 2, Ashington 1, Castle Ward R.D. 1); Nottingham, 1 (Huthwaite); Yorks West Riding, 91 (20 from Sheffield, the remainder from eight urban and rural districts, the highest figures being Keighley 33, Mexborough 15, and Doncaster 10). The West Riding of Yorkshire reported last week 61, and the previous week 45 cases. Since this return was made up ten cases of small-pox have been reported from Southport and many fresh cases from Sheffield. A fatal case has been reported from Mexborough.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 28 (0) from measles, 4 (0) from scarlet fever, 60 (16) from whooping-cough, 46 (8) from diphtheria, 51 (12) from diarrhœa and enteritis under 2 years, and 172 (72) from influenza. The figures in parentheses are those for London itself. The influenza deaths in the last five returns have been slowly rising, thus: 52, 60, 69, 86, 172—and 326 has been given verbally as the figure for the next week.

CRIPPLED CHILDREN IN CARLISLE.

A VOLUNTARY clinic for the treatment of crippled children was opened in Carlisle just over a year ago. Orthopædic work amongst the children of school age in Cumberland had been carried on for some time under the County Council, but the City Council, which is a separate authority for purposes of education and health, had not shown itself able to initiate work of this kind under existing financial conditions. As, however, the need was obvious the Council of Social Service took the matter up. The medical men of the city were invited to a conference, and promised assistance, while the Hon. Staff of the Cumberland Infirmary undertook to supervise the work. The Council then raised a sum of £500 to get the work started in premises provided by the Trustees of St. Cuthbert's Hall. A trained nurse was secured from the Oswestry Orthopædic Hospital, and the clinic was opened one day a week with an initial attendance of about 15 children, the nurse visiting the children in their homes on other days of the week. A little later the clinic was opened on two other mornings of the week for massage. By the end of the year there were 73 cripples attending the clinic; 1558 attendances had been made, and 1024 visits paid by the nurse to the homes of the children, 195 plasters had been put on, and 72 splints and instruments of various kinds supplied. These latter are supplied by the Committee, but the parents are requested to contribute towards the cost by weekly payments according to their means. Several cases found to require institutional treatment were sent to Oswestry, others requiring operations to the Cumberland Infirmary. The Health Department of the city arranged for the supply of virol at cost price in certain cases. At the outset a considerable proportion of the cases wese found to be long-standing and in need of prolonged treatment; the more recent cases, of course, yield to treatment more readily. Several cripples who previously had no earning capacity are now working in factories in the city, and providing for themselves, while others who previously were on crutches, and apparently likely to be so permanently, are now walking on their own feet. Assistance in the case of ex-servicemen's children has been granted from the United Services fund and other sources. The example of Carlisle might well be followed by other places in which the sanitary and education authorities have failed to provide for the curative treatment of their cripples.

METHODS OF TREATMENT IN EPIDEMIC ENCEPHALITIS

EPIDEMIC encephalitis made its appearance in the Philippine Islands in 1918, when three cases were recognised. In 1922 a severe epidemic of the disease occurred, cases being reported from different parts of the Islands. The first epidemic was of the lethargic type; in the second one the myoclonic type was predominant. Dr. Agerico B. M. Sison[1] made a comparative study of the different methods of treatment in the second epidemic. His first efforts were directed towards the correction of the continuous myoclonic movements which were the most distressing symptoms. Various nerve sedatives were used, such as veronal, trional, luminal, hyoscine hydrobromide, morphine sulphate and polybromide mixtures. These did not control the movements, nor had intramuscular injections of urotropine and of quinine any apparent effect. Ether anæsthesia gave temporary relief, which in one case proved permanent, the myoclonic movements not returning on the patient's recovery from anæsthesia. In the treatment of acute cases of epidemic encephalitis Dr. Sison speaks favourably of intra-spinal injection of serum obtained from patients who have just for a couple of lines in the fourth schedule there is no mention of dental treatment in the National Health Insurance Acts and the new dental organisation has at present no statutory sanction but is based on an agreement between representatives of the dental profession and the approved societies. The fact that the Ministry of Health on the invitation of the Dental Benefit Joint Committee has actually assumed responsibility for the appointment and control of the regional dental officers seems to indicate that opposition to the new scale of fees shown by certain approved societies is not taken very seriously. Figures available for December of last year show that approved societies representing 73 per cent of members eligible for dental benefit at once accepted the fees and conditions of service agreed upon by the Dental Benefit Joint Committee The societies which definitely refused to accept the scale represented only 3 per cent of eligible insured persons, and the general refusal of the dental profession to give dental treatment on any lower scale, and other considerations, have since resulted in the great majority of the doubtful societies coming into the agreement It may be taken therefore, that the initial difficulties of the scheme have been practically overcome and that a four years' experiment in dental treatment has been launched Whether a scheme involving the annual expenditure of over £2,000,000 and the professional treatment of over 10,000 000 insured persons ought to be left without some statutory control, by regulations which will have the force of law, is a matter for serious consideration

DIET AND CANCER

THE idea that diet is an important ætiological factor in cancer seems to make a strong appeal to the imagination of many writers We cannot call it an appeal to the scientific imagination because there is little scientific about it It is not based either on considerations of the pathology of the disease or on trustworthy clinical, experimental or statistical evidence. The argument begins as a rule with the assertion that cancer is rare in some particular community. The native races of Central Africa or the Esquimaux are most frequently quoted in support of the contention Since there are no vital statistics available in communities such as these, the statement at once puts out of court those inconvenient fellows, the statisticians, and makes it difficult to find anybody who from personal experience might be able to contradict the statement. So the person who makes a statement of that kind is fairly sure of getting a good innings as a "cancer expert" until the statement is investigated and found to be either untrustworthy or incorrect. Even if it were found to be true that certain races have a low incidence of cancer it would not necessarily follow that this is due to dietetic factors, since observations on animals have shown that racial differences are responsible for differences in the susceptibility to malignancy.

It would be a reasonable argument to suggest that dietetic errors may be responsible for cancer of the digestive tract It is quite feasible that such errors might produce a type of chronic irritation corresponding to that produced by tar, which leads to cancer of the skin to which it is applied There is at present no evidence in support of a view of this kind. A recent statistical inquiry by Dr M Young[1] on the incidence of cancer in men of different social classes has brought to light the interesting fact that cancer of the bowel is more prevalent in men of the best social classes, while cancer of the œsophagus and stomach is higher in men of the lowest social classes If we assume for the sake of argument that dietetic errors are responsible for cancer of the digestive tract, we would have to conclude that the dietetic errors committed by men of the highest social classes must be debited with the induction of cancer in the bowel and credited with an increased resistance to cancer of the stomach. and vice versa for the dietetic errors committed by men of the lowest social classes Dr Young's analysis, therefore, yields no evidence in support of the view that the general susceptibility to cancer of the digestive tract is affected by such dietetic differences as exist between men of the highest and the lowest social classes

But those who are trying to establish a relation between diet and cancer do not restrict their contentions to argument of this kind; they hold that a carcinoma of the stomach, of the breast, a sarcoma of the bone, and a glioma of the brain may all find their origin in diet The report on Diet and Cancer by Dr S Monckton Copeman and Prof Major Greenwood just published by the Ministry of Health, which we review in detail in another column, contributes further evidence against the view of an essential relationship between the genesis of cancer and diet In this case the incidence of cancer in enclosed monastic orders living on a vegetarian diet shows no significant difference from the incidence in the general population, although a very definite assertion to the contrary had been made The name of Prof. Greenwood is a guarantee of the soundness of the statistical argumentation. For many years Dr Copeman has been before the public as an out-spoken believer in the importance of diet in cancer At a meeting of the British Association four years ago he created a sensation in the daily press—if not among the scientific public—by suggesting that a definite relationship existed between diet (especially its content in vitamin A) and cancer. He has treated patients suffering from cancer with a special diet. It is therefore of real significance to find under his signature the following statement which occurs in the final paragraph of the conclusions: "We think a perusal of our report will convince most impartial persons that no scientific value whatever attaches to assertions supported merely by the vague pseudo-statistical evidence customarily cited respecting the rôles of certain articles of common consumption in the genesis of cancer." The authors however, propose to investigate further the apparent discrepancy noted by the late Dr. Charles Goring between the incidence of cancer in the prison and the general population

COD-LIVER OIL AND VITAMIN B

Two papers recently published,[1] by Erik Agduhr and Axel Höjer, have again brought into prominence the ill-effects of an excess of cod-liver oil in the diet. These authors find that, besides other changes, the heart is chiefly affected and that it shows brown atrophy and vacuolar degeneration of the muscle-cells Agduhr concludes that these changes are caused by some injurious substance in the cod-liver oil, but Höjer records experiments on rats proving that they are produced, not by a poison in the oil, but by giving it in overdose without simultaneously increasing the amount of vitamin B in the food The ill-effect of large doses of cod-liver oil was first observed in 1922 by R H A. Plimmer and Rosedale[2] during experiments with chicks, when it was found that the harmful action was removed by an increase of marmite (which contains vitamin B) in the food The same workers[3] have since studied in detail the relation of vitamin B to the quantity of food,[3] and have indicated that the quantity of vitamin B in the food must bear a constant ratio to the quantity of carbohydrate, fat, and protein in the diet. They consider it impossible to speak of the requirement of vitamin B in terms of a daily dose as is usually supposed It has also been pointed out by Plimmer and Rosedale[4] that deficiency of vitamin B must quickly transferred to half-cream or skimmed-milk mixtures at any sign of intolerance to food the sugar being also reduced to some extent Every infant who is failing to gain weight during the warm weather ought to be looked on as a potential victim of summer diarrhœa The boiling of all bottles teats, and cooking utensils, and the prevention of contamination of the food, should be stressed but not placed first. Dr. Ronald Carter's method of early notification of such cases with visiting of their homes by trained health-visitors is admirable At the onset a simple purge with castor oil, which tends to leave the infant constipated and 24 hours—not longer—on half-strength saline or plain boiled water containing a small amount of sugar, give the stomach and bowel an opportunity to recover. The return to a normal diet should be gradual, and a diet low in fat is strongly indicated Commercially supplied dried buttermilk is very useful in the early days, and skimmed lactic-acid milk made according to[3] Marriott's formula is also valuable This formula is as follows to one pint of boiled skimmed milk and half a pint of boiled water, 60 drops of (B P) lactic acid are added drop by drop, the mixture being stirred continuously This mixture must not be heated above blood temperature or it will curdle A suitable quantity of sugar is added, and feeds of appropriate size are given Severe cases of summer diarrhœa must be treated in institutions If summer diarrhœa could be made universally notifiable the mortality would undoubtedly be greatly lowered The prevention, however, lies in further educating the public to the welfare movement, and in the value of good hygiene and feeding In this way the proportion of infants underweight and ailing should grow less, and it is these cases which are most difficult to deal with medically.

THE MEDICAL DEPARTMENT OF THE U S ARMY

Major-General Merritte Weber Ireland who will be remembered here as Chief Surgeon of the U S Expeditionary Force in 1918 has been reappointed Surgeon of the Army of the United States for a third period of four years This presages, it is believed, considerable changes in the Medical Department of that army, which in time of war aggregates 20 per cent of all officers mobilised and 10 per cent of all enlisted men The Surgeon-General has written[4] to the Adjutant-General stating that the acute shortage of personnel has become well-nigh intolerable, the staff being over-worked to the limit of human endurance, in spite of the fact that the Medical Department is an asset rather than a liability, and therefore should not be unduly limited, for it is a national insurance, saving life, preventing disease, and diminishing claims for pension or compensation The Surgeon-General proposes that the Medical Department shall consist of six general officers (one major-general, five brigadier-generals—three for the Medical Corps, one dental, one veterinary), and five sections (1) the *Medical Corps* of 1820 officers, from colonel downwards, (2) the *Dental Corps* of 560 officers, (3) the *Veterinary Corps* of 250 officers and 1500 other ranks, (4) the *Nurse Corps* of 700, its superintendent with relative rank as colonel, chief nurses as captains, head nurses as first, and nurses as second lieutenants, (5) the *Medical Auxiliary Corps*, 140 officers and 13,500 other ranks, corresponding to the orderlies of the R A M C, though separated from the medical officers, who are by themselves in the Medical Corps The officers of the auxiliary corps seem to be those corresponding to the quartermasters R A M C, along with the non-medical officers—surveyors, engineers, chemists—who are given commissions within the medical department to advance the hygiene of the army, and traders in medical supplies, to facilitate the acquirement of the necessary medical stores especially after mobilisation As there is no war at present, only 544 officers and 2050 additional men are required at once The medical department of the U S Army serves also the Air Corps, "contract physicians" (no longer "contract surgeons") being employed as required "Surgeon" is being employed as a staff title, not as a mark of professional attainment

NIELS THORKILD ROVSING.

THE death is announced from Copenhagen of Dr Thorkild Rovsing professor of clinical surgery and sometime Rector of the University, at the early age of 64 years He died in his own private hospital after operation for cancer of the throat. Prof Rovsing was born in 1862 at Flensborg, was educated at Copenhagen, and entering the surgical service of the Royal Frederick Hospital, soon became its leading spirit on the surgical side, and finally chairman of the board of management He was for a long while President of the Danish Surgical Society and a corresponding member of medical societies in the neighbouring countries His first important publication dealt with inflammations of the urinary bladder and between 1895 and 1910 appeared the three volumes of his standard work on the surgical diseases of the urinary organs Later he published a volume on abdominal surgery His work on appendicitis attached his name to a diagnostic symptom, about the value of which there was a sharp discussion 20 years ago More recently his interest centred on the gall bladder, and he collected material wherewith to refute Naunyn's teaching that stones only arise in an infected bladder; analysis of his own 530 cases all went to show that there is a small nucleus of pigment at the core of every stone, while in more than half the cases the contents of the gall-bladder were sterile As a result of this work he remained a stalwart opponent of cholecystectomy In some other directions his surgical methods attracted notice, as in his treatment of arthritis by injections of vaseline and an ingenious method of gastropexy His literary activities were many-sided, for he edited with great success the *Hospitalstidende*, a weekly journal containing original papers and reviews of medical literature Latterly he took a prominent part in the campaign against cancer in Denmark, and was for a time a member of the short-lived Government of 1920 although, happily for surgery, his political career lasted only a few days Dr Rovsing's two sons are in the medical profession His death removes one of the principal attractions of the Copenhagen Medical School to visitors from abroad

DENTAL BENEFIT

THE position of dental treatment as an additional benefit under the National Health Insurance Acts seems to have become remarkably stable, if it may be judged from the various circulars issued by the Ministry of Health and the Board of Health for Scotland Circular A.S 259, the most recent of these documents, sets forth the latest decisions arrived at by the Dental Benefit Joint Committee, and it appears from them that the system evolved for administration of voluntary benefit bears a fairly close resemblance to that which governs statutory medical benefit The dental societies have apparently been able to set up a representative committee to look after the interests of dentists, and this will work in much the same way as the panel committee works under the medical scheme The Dental Benefit Joint Committee has functions generally analogous to those of local insurance committees, and has a subcommittee whose duties resemble those of the medical services subcommittee Lastly come the regional dental officers, whose posts are, of course, modelled on those of regional medical officers; seven of them are now being selected, and will act in areas whose centres will probably be London, Manchester Birmingham, Leeds, Cardiff, and Glasgow Except for a couple of lines in the fourth schedule there is no mention of dental treatment in the National Health Insurance Acts and the new dental organisation has at present no statutory sanction, but is based on an agreement between representatives of the dental profession and the approved societies. The fact that the Ministry of Health, on the invitation of the Dental Benefit Joint Committee, has actually assumed responsibility for the appointment and control of the regional dental officers seems to indicate that opposition to the new scale of fees shown by certain approved societies is not taken very seriously. Figures available for December of last year show that approved societies representing 73 per cent. of members eligible for dental benefit at once accepted the fees and conditions of service agreed upon by the Dental Benefit Joint Committee. The societies which definitely refused to accept the scale represented only 3 per cent. of eligible insured persons and the general refusal of the dental profession to give dental treatment on any lower scale, and other considerations, have since resulted in the great majority of the doubtful societies coming into the agreement. It may be taken, therefore, that the initial difficulties of the scheme have been practically overcome, and that a four years' experiment in dental treatment has been launched. Whether a scheme involving the annual expenditure of over £2,000,000 and the professional treatment of over 10,000,000 insured persons ought to be left without some statutory control by regulations which will have the force of law, is a matter for serious consideration.

DIET AND CANCER

THE idea that diet is an important ætiological factor in cancer seems to make a strong appeal to the imagination of many writers. We cannot call it an appeal to the scientific imagination because there is little scientific about it. It is not based either on considerations of the pathology of the disease or on trustworthy clinical, experimental or statistical evidence. The argument begins as a rule with the assertion that cancer is rare in some particular community. The native races of Central Africa or the Esquimaux are most frequently quoted in support of the contention. Since there are no vital statistics available in communities such as these, the statement at once puts out of court those inconvenient fellows, the statisticians, and makes it difficult to find anybody who from personal experience might be able to contradict the statement. So the person who makes a statement of that kind is fairly sure of getting a good innings as a "cancer expert" until the statement is investigated and found to be either untrustworthy or incorrect. Even if it were found to be true that certain races have a low incidence of cancer it would not necessarily follow that this is due to dietetic factors, since observations on animals have shown that racial differences are responsible for differences in the susceptibility to malignancy.

It would be a reasonable argument to suggest that dietetic errors may be responsible for cancer of the digestive tract. It is quite feasible that such errors might produce a type of chronic irritation corresponding to that produced by tar, which leads to cancer of the skin to which it is applied. There is at present no evidence in support of a view of this kind. A recent statistical inquiry by Dr. M. Young[1] on the incidence of cancer in men of different social classes has brought to light the interesting fact that cancer of the bowel is more prevalent in men of the best social classes, while cancer of the œsophagus and stomach is higher in men of the lowest social classes. If we assume for the sake of argument that dietetic errors are responsible for cancer of the digestive tract, we would have to conclude that the dietetic errors committed by men of the highest social classes must be debited with the induction of cancer in the bowel and credited with an increased resistance to cancer of the stomach, and vice versa for the dietetic errors committed by men of the lowest social classes. Dr. Young's analysis, therefore, yields no evidence in support of the view that the general susceptibility to cancer of the digestive tract is affected by such dietetic differences as exist between men of the highest and the lowest social classes.

But those who are trying to establish a relation between diet and cancer do not restrict their contentions to argument of this kind; they hold that a carcinoma of the stomach, of the breast, a sarcoma of the bone, and a glioma of the brain may all find their origin in diet. The report on Diet and Cancer by Dr. S. Monckton Copeman and Prof. Major Greenwood just published by the Ministry of Health, which we review in detail in another column, contributes further evidence against the view of an essential relationship between the genesis of cancer and diet. In this case the incidence of cancer in enclosed monastic orders living on a vegetarian diet shows no significant difference from the incidence in the general population, although a very definite assertion to the contrary had been made. The name of Prof. Greenwood is a guarantee of the soundness of the statistical argumentation. For many years Dr. Copeman has been before the public as an out-spoken believer in the importance of diet in cancer. At a meeting of the British Association four years ago he created a sensation in the daily press—if not among the scientific public—by suggesting that a definite relationship existed between diet (especially its content in vitamin A) and cancer. He has treated patients suffering from cancer with a special diet. It is therefore of real significance to find under his signature the following statement which occurs in the final paragraph of the conclusions: "We think a perusal of our report will convince most impartial persons that no scientific value whatever attaches to assertions supported merely by the vague pseudo-statistical evidence customarily cited respecting the rôles of certain articles of common consumption in the genesis of cancer." The authors, however, propose to investigate further the apparent discrepancy noted by the late Dr. Charles Goring between the incidence of cancer in the prison and the general population.

COD-LIVER OIL AND VITAMIN B

TWO papers recently published,[1] by Erik Agduhr and Axel Hojer, have again brought into prominence the ill-effects of an excess of cod-liver oil in the diet. These authors find that, besides other changes, the heart is chiefly affected and that it shows brown atrophy and vacuolar degeneration of the muscle-cells. Agduhr concludes that these changes are caused by some injurious substance in the cod-liver oil, but Hojer records experiments on rats proving that they are produced, not by a poison in the oil, but by giving it in overdose without simultaneously increasing the amount of vitamin B in the food. The ill-effect of large doses of cod-liver oil was first observed in 1922 by R. H. A. Plimmer and Rosedale[2] during experiments with chicks, when it was found that the harmful action was removed by an increase of marmite (which contains vitamin B) in the food. The same workers[3] have since studied in detail the relation of vitamin B to the quantity of food,[3] and have indicated that the quantity of vitamin B in the food must bear a constant ratio to the quantity of carbohydrate, fat, and protein in the diet. They consider it impossible to speak of the requirement of vitamin B in terms of a daily dose as is usually supposed. It has also been pointed out by Plimmer and Rosedale[4] that deficiency of vitamin B must quickly transferred to half-cream or skimmed-milk mixtures at any sign of intolerance to food, the sugar being also reduced to some extent. Every infant who is failing to gain weight during the warm weather ought to be looked on as a potential victim of summer diarrhœa. The boiling of all bottles, teats, and cooking utensils, and the prevention of contamination of the food, should be stressed but not placed first. Dr Ronald Carter's method of early notification of such cases with visiting of their homes by trained health-visitors is admirable. At the onset a simple purge with castor oil, which tends to leave the infant constipated, and 24 hours—not longer—on half-strength saline or plain boiled water containing a small amount of sugar, give the stomach and bowel an opportunity to recover. The return to a normal diet should be gradual, and a diet low in fat is strongly indicated. Commercially supplied dried buttermilk is very useful in the early days, and skimmed lactic-acid milk made according to[3] Marriott's formula is also valuable. This formula is as follows: to one pint of boiled skimmed milk and half a pint of boiled water, 60 drops of (B P.) lactic acid are added drop by drop, the mixture being stirred continuously. This mixture must not be heated above blood temperature or it will curdle. A suitable quantity of sugar is added, and feeds of appropriate size are given. Severe cases of summer diarrhœa must be treated in institutions. If summer diarrhœa could be made universally notifiable the mortality would undoubtedly be greatly lowered. The prevention, however, lies in further educating the public to the welfare movement, and in the value of good hygiene and feeding. In this way the proportion of infants underweight and ailing should grow less, and it is these cases which are most difficult to deal with medically.

THE MEDICAL DEPARTMENT OF THE U S ARMY

Major-General Merritte Weber Ireland, who will be remembered here as Chief Surgeon of the U S Expeditionary Force in 1918, has been reappointed Surgeon of the Army of the United States for a third period of four years. This presages, it is believed, considerable changes in the Medical Department of that army, which in time of war aggregates 20 per cent of all officers mobilised and 10 per cent of all enlisted men. The Surgeon-General has written[4] to the Adjutant-General stating that the acute shortage of personnel has become well-nigh intolerable, the staff being over-worked to the limit of human endurance, in spite of the fact that the Medical Department is an asset rather than a liability, and therefore should not be unduly limited, for it is a national insurance, saving life, preventing disease, and diminishing claims for pension or compensation. The Surgeon-General proposes that the Medical Department shall consist of six general officers (one major-general, five brigadier-generals—three for the Medical Corps, one dental, one veterinary), and five sections. (1) the *Medical Corps* of 1820 officers, from colonel downwards, (2) the *Dental Corps* of 560 officers, (3) the *Veterinary Corps* of 250 officers and 1500 other ranks, (4) the *Nurse Corps* of 700, its superintendent with relative rank as colonel, chief nurses as captains, head nurses as first, and nurses as second lieutenants, (5) the *Medical Auxiliary Corps*, 140 officers and 13,500 other ranks, corresponding to the orderlies of the R A M C, though separated from the medical officers, who are by themselves in the Medical Corps. The officers of the auxiliary corps seem to be those corresponding to the quartermasters, R A.M C, along with the non-medical officers—surveyors, engineers, chemists—who are given commissions within the medical department to advance the hygiene of the army, and traders in medical supplies, to facilitate the acquirement of the necessary medical stores, especially after mobilisation. As there is no war at present, only 544 officers and 2050 additional men are required at once. The medical department of the U S Army serves also the Air Corps, "contract physicians" (no longer "contract surgeons") being employed as required. "Surgeon" is being employed as a staff title, not as a mark of professional attainment.

NIELS THORKILD ROVSING.

The death is announced from Copenhagen of Dr Thorkild Rovsing, professor of clinical surgery and sometime Rector of the University, at the early age of 64 years. He died in his own private hospital after operation for cancer of the throat. Prof. Rovsing was born in 1862 at Flensborg, was educated at Copenhagen, and entering the surgical service of the Royal Frederick Hospital, soon became its leading spirit on the surgical side, and finally chairman of the board of management. He was for a long while President of the Danish Surgical Society and a corresponding member of medical societies in the neighbouring countries. His first important publication dealt with inflammations of the urinary bladder, and between 1895 and 1910 appeared the three volumes of his standard work on the surgical diseases of the urinary organs. Later he published a volume on abdominal surgery. His work on appendicitis attached his name to a diagnostic symptom, about the value of which there was a sharp discussion 20 years ago. More recently his interest centred on the gall bladder, and he collected material wherewith to refute Naunyn's teaching that stones only arise in an infected bladder, analysis of his own 530 cases all went to show that there is a small nucleus of pigment at the core of every stone, while in more than half the cases the contents of the gall-bladder were sterile. As a result of this work he remained a stalwart opponent of cholecystectomy. In some other directions his surgical methods attracted notice, as in his treatment of arthritis by injections of vaseline and an ingenious method of gastropexy. His literary activities were many-sided, for he edited with great success the *Hospitalstidende*, a weekly journal containing original papers and reviews of medical literature. Latterly he took a prominent part in the campaign against cancer in Denmark, and was for a time a member of the short-lived Government of 1920, although, happily for surgery, his political career lasted only a few days. Dr Rovsing's two sons are in the medical profession. His death removes one of the principal attractions of the Copenhagen Medical School to visitors from abroad.

DENTAL BENEFIT

The position of dental treatment as an additional benefit under the National Health Insurance Acts seems to have become remarkably stable, if it may be judged from the various circulars issued by the Ministry of Health and the Board of Health for Scotland. Circular A.S 259, the most recent of these documents, sets forth the latest decisions arrived at by the Dental Benefit Joint Committee, and it appears from them that the system evolved for administration of voluntary benefit bears a fairly close resemblance to that which governs statutory medical benefit. The dental societies have apparently been able to set up a representative committee to look after the interests of dentists, and this will work in much the same way as the panel committee works under the medical scheme. The Dental Benefit Joint Committee has functions generally analogous to those of local insurance committees, and has a subcommittee whose duties resemble those of the medical services subcommittee. Lastly come the regional dental officers, whose posts are, of course, modelled on those of regional medical officers, seven of them are now being selected, and will act in areas whose centres will probably be London, Manchester, Birmingham, Leeds, Cardiff, and Glasgow. Except for a couple of lines in the fourth schedule there is no mention of dental treatment in the National Health Insurance Acts and the new dental organisation has at present no statutory sanction but is based on an agreement between representatives of the dental profession and the approved societies The fact that the Ministry of Health on the invitation of the Dental Benefit Joint Committee, has actually assumed responsibility for the appointment and control of the regional dental officers seems to indicate that opposition to the new scale of fees shown by certain approved societies is not taken very seriously Figures available for December of last year show that approved societies representing 73 per cent of members eligible for dental benefit at once accepted the fees and conditions of service agreed upon by the Dental Benefit Joint Committee The societies which definitely refused to accept the scale represented only 3 per cent of eligible insured persons and the general refusal of the dental profession to give dental treatment on any lower scale, and other considerations, have since resulted in the great majority of the doubtful societies coming into the agreement It may be taken therefore, that the initial difficulties of the scheme have been practically overcome and that a four years' experiment in dental treatment has been launched. Whether a scheme involving the annual expenditure of over £2,000,000 and the professional treatment of over 10,000 000 insured persons ought to be left without some statutory control. by regulations which will have the force of law, is a matter for serious consideration.

DIET AND CANCER

THE idea that diet is an important ætiological factor in cancer seems to make a strong appeal to the imagination of many writers We cannot call it an appeal to the scientific imagination because there is little scientific about it It is not based either on considerations of the pathology of the disease or on trustworthy clinical, experimental or statistical evidence. The argument begins as a rule with the assertion that cancer is rare in some particular community. The native races of Central Africa or the Esquimaux are most frequently quoted in support of the contention Since there are no vital statistics available in communities such as these, the statement at once puts out of court those inconvenient fellows, the statisticians, and makes it difficult to find anybody who from personal experience might be able to contradict the statement So the person who makes a statement of that kind is fairly sure of getting a good innings as a "cancer expert" until the statement is investigated and found to be either untrustworthy or incorrect Even if it were found to be true that certain races have a low incidence of cancer it would not necessarily follow that this is due to dietetic factors, since observations on animals have shown that racial differences are responsible for differences in the susceptibility to malignancy.

It would be a reasonable argument to suggest that dietetic errors may be responsible for cancer of the digestive tract It is quite feasible that such errors might produce a type of chronic irritation corresponding to that produced by tar, which leads to cancer of the skin to which it is applied There is at present no evidence in support of a view of this kind. A recent statistical inquiry by Dr M Young[1] on the incidence of cancer in men of different social classes has brought to light the interesting fact that cancer of the bowel is more prevalent in men of the best social classes, while cancer of the œsophagus and stomach is higher in men of the lowest social classes If we assume for the sake of argument that dietetic errors are responsible for cancer of the digestive tract, we would have to conclude that the dietetic errors committed by men of the highest social classes must be debited with the induction of cancer in the bowel and credited with an increased resistance to cancer of the stomach, and vice versa for the dietetic errors committed by men of the lowest social classes Dr Young's analysis, therefore, yields no evidence in support of the view that the general susceptibility to cancer of the digestive tract is affected by such dietetic differences as exist between men of the highest and the lowest social classes

But those who are trying to establish a relation between diet and cancer do not restrict their contentions to argument of this kind, they hold that a carcinoma of the stomach, of the breast. a sarcoma of the bone, and a glioma of the brain may all find their origin in diet. The report on Diet and Cancer by Dr. S Monckton Copeman and Prof Major Greenwood just published by the Ministry of Health which we review in detail in another column, contributes further evidence against the view of an essential relationship between the genesis of cancer and diet In this case the incidence of cancer in enclosed monastic orders living on a vegetarian diet shows no significant difference from the incidence in the general population, although a very definite assertion to the contrary had been made The name of Prof. Greenwood is a guarantee of the soundness of the statistical argumentation. For many years Dr Copeman has been before the public as an out-spoken believer in the importance of diet in cancer At a meeting of the British Association four years ago he created a sensation in the daily press—if not among the scientific public—by suggesting that a definite relationship existed between diet (especially its content in vitamin A) and cancer He has treated patients suffering from cancer with a special diet It is therefore of real significance to find under his signature the following statement which occurs in the final paragraph of the conclusions: "We think a perusal of our report will convince most impartial persons that no scientific value whatever attaches to assertions supported merely by the vague pseudo-statistical evidence customarily cited respecting the rôles of certain articles of common consumption in the genesis of cancer." The authors however. propose to investigate further the apparent discrepancy noted by the late Dr. Charles Goring between the incidence of cancer in the prison and the general population.

COD-LIVER OIL AND VITAMIN B

Two papers recently published[1] by Erik Agduhr and Axel Höjer, have again brought into prominence the ill-effects of an excess of cod-liver oil in the diet These authors find that, besides other changes, the heart is chiefly affected and that it shows brown atrophy and vacuolar degeneration of the muscle-cells Agduhr concludes that these changes are caused by some injurious substance in the cod-liver oil, but Höjer records experiments on rats proving that they are produced, not by a poison in the oil, but by giving it in overdose without simultaneously increasing the amount of vitamin B in the food The ill-effect of large doses of cod-liver oil was first observed in 1922 by R. H A. Plimmer and Rosedale[2] during experiments with chicks, when it was found that the harmful action was removed by an increase of marmite (which contains vitamin B) in the food The same workers[3] have since studied in detail the relation of vitamin B to the quantity of food,[3] and have indicated that the quantity of vitamin B in the food must bear a constant ratio to the quantity of carbohydrate, fat, and protein in the diet. They consider it impossible to speak of the requirement of vitamin B in terms of a daily dose as is usually supposed It has also been pointed out by Plimmer and Rosedale[4] that deficiency of vitamin B must be considered in two different ways, depending upon its degree. They state that if the deficiency is complete, or nearly so, the symptoms of beri-beri result more or less rapidly and end fatally, if, however, the deficiency is only small the typical symptoms of beri-beri do not appear, but in a shorter or longer time there are signs of gastro-intestinal disturbance, appendicitis, and cardiac troubles, which become chronic and may end in death. If these results be accepted it becomes of great importance to know if the ordinary daily diet contains an adequate quantity of vitamin B. Various foods are being tested by Plimmer and Rosedale, and their preliminary data suggest that at least half the daily diet must consist of wholemeal flour or whole cereal or pulses, to avoid symptoms from the heart or gastro-intestinal tract. They state that the everyday diet, consisting mainly of white flour, sugar, fat, and meat, does not contain an ample supply of vitamin B and they consider it very likely that the cardiac disorders, constipation, and gastro-intestinal symptoms nowadays so common are produced by a deficiency of vitamin B in the daily food.

ANÆSTHETIC FATALITIES AND STATISTICS

THE two contributions relating to anæsthetics (published on the opening page of this issue and p 173 respectively) give food for serious speculation. In some respects they are so contradictory. The very fact that there should be a post-graduate lecture on anæsthetics is in opposition to Dr Goodman Levy's affirmative that "little or nothing has been effected in the way of reducing the general liability to death under anæsthetics." It is generally admitted that as regards the safety of anæsthetic administration there is no other factor which rivals in effect the knowledge and experience of the anæsthetist. This must depend to a great extent on his education in the matter, and there has been much advance in education of recent years. Every student nowadays is obliged to acquire a certain amount of training in anæsthetics before he can be correctly signed up for his final examinations, and those who proceed to hold resident appointments generally acquire a really useful amount of practical experience in the giving of anæsthetics. It is quite true that the number of anæsthetic fatalities per annum remains a formidable figure. We have, however, no considerable evidence, supplied by Dr. Levy or elsewhere, that it does not represent a falling proportion when compared with the total number of operations performed. This increases constantly and so, moreover, does the magnitude of the operations—which can be easily judged by an inspection of the daily list of operations at a few leading hospitals. Whereas in the past these lists would have been found to present a large proportion of operations for hernia, varicose veins, and similar comparatively trivial proceedings, to-day they include more generally major abdominal operations and extensive proceedings for the eradication of malignant disease. An increase in the whole number of operations performed, and a notable increase in the severity of these operations, might lead to an increased actual mortality without there being any proportional increase, and without there being any blameworthy defects in the anæsthesia. Much greater operative risks, in fact, are probably run to-day than were ever ventured on by surgeons in the past. They are often rewarded by life-saving, but they are paid for by an increased operative mortality. We are aware that this argument does not meet Dr Levy's affirmation that many of the deaths that are recorded as occurring under ether were in connexion with trivial operations. No mention, however, is made of the state of the patients at the time. Obviously, even a trivial operation may be an extremely serious affair where the subject of it is in a critical condition from some disorder, very likely unconnected with that for which he is undergoing operation. It is hard to believe—certainly our own observation gives no support to the idea—that there are frequent deaths from the administration of ether to individuals in ordinary health undergoing trivial operations. Dr Levy begs the question by suggesting that the deaths recorded as arising under ether anæsthesia really occurred owing to the use of some other anæsthetic. In this way, of course, it would be easy to explain away the entire collection of statistics on which his remarks are based. If when ether is mentioned the truth is that chloroform was used, why should it not be true that when the death certificate describes a patient's heart as "normal," it was actually the seat of myocardial degeneration? Nevertheless, we have much sympathy with Dr Levy's attempt to explain an apparently extraordinary figure. Generally speaking, the increased number of deaths under ether is, of course, due to the enormously increased use of this drug as a routine anæsthetic agent in the place of the chloroform or the "mixture" of the past. It is probably true that some deaths after prolonged ether inhalation arise from an excessive administration, owing to an unsuspecting belief in the complete innocuousness of ether. It should be realised that ether is toxic and can be lethal, even though it is not easy to bring about death on the table in the case of healthy subjects. Conditioned by considerations of this kind the trust in ether is justifiable, and will not, we hope, be shaken.

IMMUNITY IN SYPHILIS

AN annotation in THE LANCET last week (p 145) described some experiments on superinfection with syphilis, and it may be of interest to recall some recent observations on immunity to this disease. John Hunter (1810) showed experimentally that when the skin of a person with manifest generalised syphilis is scarified and inoculated with material from a secondary syphilitic lesion no lesion is produced at the site of scarification. This demonstration in vivo was the earliest experimental evidence of acquired resistance to syphilis. Dr Alan M Chesney[1] has recently reviewed the recorded observations and experiments of the workers in many countries who have, since Hunter, attempted to solve the problem of immunity in syphilis. Dr Chesney's own experimental studies of this subject are not the least noteworthy among them. His critical analysis of the protocols of experiments and the conclusions based thereon is a valuable contribution to syphilology. He finds that all the reinoculation experiments carried out upon syphilitic human beings, monkeys and rabbits, since the discovery of *Spirochæta pallida*, show that the host gradually acquires a resistance, more or less incomplete, toward a second infection with the same parasite if the disease be allowed to develop untreated. This resistant state is already present before the primary lesion has healed and it lasts for the rest of the host's life, though subject to periodical fluctuations. Not all tissues of the body, however, share equally in this resistance, and in rabbits it is more effective against homologous than heterologous strains of spirochæte. The passage of time appears to be essential for the acquisition of this resistant state. Neisser's experiments on monkeys led him to the belief that acquired immunity in syphilis depends upon foci of syphilis somewhere in the body. Analysis of his experiments in the light of experimental results in the rabbit indicates rather that in syphilis an immunity may develop which is not dependent upon the persistence of foci of infection, and this is in harmony with clinical experience of reinfections in man. This phase of the problem is still open to solution. Yet there is evidence that during the course of a syphilitic infection the host acquires some resistance against a second infection with the same species of parasite, which may persist after the first infection has been reduced by treatment to the level where it cannot be detected. Reinoculation tests in animals and reinfections in man have, therefore, no real bearing upon the question of persistence or absence of infection—i.e., of cure or failure to cure—and are useful only as indicators of specific resistance. All workers, employing no matter what antigen, have failed to produce active immunity to syphilis in man, monkeys, or rabbits. Nor has it proved possible to alter the course of an existing syphilitic infection by immunisation with any product derived from cultures of spirochæte or from syphilitic tissue. There is no convincing evidence that the offspring of syphilitic parents are immune to syphilis and at the same time free of syphilitic infection. There is no hope, therefore, that the human race may build up a heightened resistance to the disease. Neisser observed that in lands where syphilis has prevailed for generations its course is not appreciably different from that in countries where it is not so prevalent. The records of the development of antibodies in syphilitic patients are conflicting. Indeed it is far from clear that these so-called antibodies have anything to do with recovery from syphilis or with acquired or natural resistance to the disease. Certain antibodies can be produced in the rabbit; they give but little protection, however, for the very animal possessing them in its serum is found to be susceptible to infection with potent virus. F. Jahnel and J. Lange (1925) inoculated four paretics with a yaws virus which was evidently virulent for it produced yaws lesions in a normal person. In none of the paretics did a lesion develop. There is some epidemiological evidence for the view that in man yaws protects against syphilis, although the simultaneous existence of both infections in the same person has been reported. Recent work with rabbits suggests a close biological relationship between the two. If it be true that yaws can protect a man against syphilis the tropics may yet produce a new Jenner who will find a way of protecting man against syphilis by systematic inoculation with yaws virus. Venereal spirochætosis of rabbits deserves attention because of the possibility of confusing it with experimental syphilis in the rabbit. It is indigenous to rabbits, manifesting itself as a chronic dermatitis of genitalia and anus. It is transmissible from rabbit to rabbit by sexual intercourse, whereas syphilis in rabbits is not so transmissible. Its causative agent, the *Spirochæta cuniculi* is morphologically indistinguishable from *S. pallida*. There is no evidence of immunological relationship between the two. Rabbits infected with either are suceptible to infection with the other. It is certain that the tissues of the syphilitic acquire the capacity to react to new syphilitic virus introduced from without, and also to the syphilitic's own virus, in a manner different from that displayed by the normal individual. It may be manifested as apparent indifference (anergy) or by super-susceptibility (allergy). Both may be functions of the defensive process. Spontaneous sterilising immunity in syphilis must be rare; man, as a rule, is incapable of eliminating syphilis from his body unaided, though he does react against it and limit its extent. That this reaction is incomplete may be due in part to an immunisation of the invading organism against the host, a mutual adjustment between the two being arrived at whereby a state of ideal parasitism is nearly reached; or else it may be due to some similarity between the metabolic activities of the spirochætes and the host's cells.

[1] Medicine Analytical Reviews of General Medicine Neurology and Pediatrics vol v, No 4. Obtainable in Great Britain from Messrs Baillière, Tindall and Cox 7, Henrietta-street, London.

WE are glad to announce that the slight improvement in Sir Ernest Hodder-Williams's condition is being maintained.

THE death occurred at Cheltenham on Jan. 14th of Dr. Thomas Claye Shaw, formerly medical superintendent of the London County Asylum at Banstead and a pioneer in mental welfare. He was 81 years of age.

THE Home Secretary has appointed Dr. John Crosthwaite Bridge, one of the Medical Inspectors of the Factory Department to the post of Senior Medical Inspector of Factories which was vacated by the resignation of Sir Thomas Legge.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCVII.—TUBERCULOSIS OF THE HIP-JOINT IN CHILDREN.

A SUCCESSFUL result in cases of tuberculosis of the hip depends so largely on early treatment, constitutional as well as local, that the recognition of the disease in an early stage is of great importance. In young children it is almost always the limp which gives rise to suspicion, although in older children and adults pain in the knee or hip on sudden forced movements of the joint may be an equally early symptom. A constant accompaniment is some limitation of movement, due to reflex muscular spasm; when the sound hip and knee are flexed until the lumbar lordosis is obliterated, it will be found that the child cannot lay his other leg flat on the table and further, that gentle attempts at rotation and abduction to the degree obtainable with the sound limb lead to movement of the pelvis. Limitation of movement in every direction indicates arthritis but this is not necessarily tuberculous, and other conditions have to be excluded. A transient toxic arthritis, secondary to tonsillar or intestinal infection, is not infrequent, but this clears up completely after a short rest in bed. Gonococcal arthritis and monarticular rheumatism are uncommon in the hip-joint. Acute osteomyelitis of the upper end of the femur is characterised by severe toxic symptoms and cocci are found in any pus obtained by aspiration; X ray and clinical examination distinguishes pseudocoxalgia, traumatic coxa vara, osteo-arthritis, tumours, fibrocystic disease, and disease of the fifth lumbar vertebra or sacro-iliac joint, all conditions which may give rise to symptoms suggesting tuberculosis of the hip-joint. Apart from these, almost all suspected cases prove to be tuberculous and the only way to guard against an error which may have serious consequences is to adopt the principle that children in whom pain or limitation of movement persists in spite of rest in bed for a few weeks should receive the treatment advocated for a tuberculous joint unless X ray examination reveals the presence of another disease. A negative skiagram does not prove the absence of tuberculosis in an early stage. A negative von Pirquet test, should it be obtained, is, on the other hand, useful evidence that the condition is not tuberculous.

A diagnosis of early tuberculosis of the hip having been made the transfer of the patient to suitable surroundings should be regarded as most urgent. It is generally accepted that the disease usually begins in the red marrow of the head and neck of the femur and the acetabulum, and that early reflex spasm of the hip muscles may be due to sympathetic inflammation of the joint before this has itself become actually infected with tubercle. This is the time, while the disease is still limited to the interior of the bone, to apply constitutional treatment intensively—change of air and environment, continuous life in the open air with exposure to sunshine or artificial light, good food, and cod-liver oil—combined with effective traction. London at any rate, is well supplied with institutions at which such treatment is available, and there is no need for delay, for if application is made by telephone to the London County Council any case of hip tuberculosis will be transferred by ambulance to one of the country orthopædic hospitals of the Metropolitan Asylums Board forthwith. At a few institutions such as the Shropshire Orthopædic Hospital, Oswestry, rooms are reserved for paying patients. For children of the middle and upper classes treatment combined with suitable educational facilities can now be obtained at the Morland Clinics at Alton, Hampshire, where during the summer months the amount of sunshine available for treatment is high, and the mildness of the climate makes outdoor life possible during the greater part of the year without discomfort to the patients

There has been a tendency in recent years to attribute the benefits of heliotherapy mostly to the light It is probable that this is an incorrect assumption, and that the marked influence on metabolism of exposure of limited parts of the body to movements of air and to changes of temperature is of even greater importance. In this land of limited sunshine, experience shows that, provided the cases come under adequate treatment at an early stage, results unsurpassed in any country can be obtained by an open-air life reinforced during the winter months by artificial light in graduated doses To obtain the best effect outdoor life should be continuous, the appetite and weight show immediate improvement, anæmia speedily disappears, while respiratory troubles and spread of infectious disease are almost unknown In winter the child should have a small blanket next him, with hot-water bottles or loose blanket-bags for the feet and woollen gloves or mittens for the hands With ordinary care it is only occasionally that the sunshine in this country will cause troublesome sunburn, and when it does occur it does not appear to cause ill-effect apart from the local discomfort At the slightest sign of it the patient should be covered and the reddened skin treated with calamine lotion It is unnecessary here, therefore, to follow the elaborate system of carefully graduated exposures required in Switzerland, nevertheless, it is advisable that at the commencement of the treatment exposures should be gradual both as to the extent of surface and the period, particularly with children newly received from towns In hot weather the patient should be placed in the shade during the heat of the day; the head should be protected by hat or sunshade, and the eyes should be directed away from the sun and, if necessary, tinted glasses should be worn

Methods of Immobilisation and Extension

Immobilisation in the active stage is now universal Ambulatory treatment is bad, not only because it encourages growth in the sound limb in excess of the affected one, but on account of the difficulty of fixing the joint and preventing deformity As is evident from X ray examination, decalcification of the affected bones occurs early, and for this reason imperfect fixation, leading to reflex spasm and pressure on the softened bones, is most harmful Even absolute fixation, however, does not remove a tonic contraction of these muscles, and thus traction in some form or other is needed. Weight-can extension may be used, but traction by suspension will generally be found more effective In its simplest form the ~~mattress~~, resting for its whole length on a fracture-board, is raised at one end to the level of the top rail of the bedstead head. and the cord of a strapping extension, applied to the thigh of the affected limb, is tied to the rail The weight extending the joint is thus the patient's body, and it is remarkable how in a single night an acutely tender and markedly malposed joint will painlesly fall into good position Slight flexion of the knee is secured by the insertion of a wooden bar under the mattress, and external rotation is prevented by a sandal, to the sole of which a piece of wire, bent to the shape of an inverted T, is screwed This method of treatment is suitable when the patient shows an average amount of constitutional resistance, the disease is comparatively recent, and general thickening is absent or inconsiderable, even though there may be localised abscess formation When, on the other hand, there is found on admission marked general thickening around the joint with considerable pain and tenderness, and the patient appears to have little power of resisting the disease and to be definitely ill with it, or if septic sinuses are already present, it is hopeless to expect a usefully movable joint, and a Jones's abduction frame is probably the most generally convenient splint Whichever of these two methods is indicated at first, the time will arrive when the joint may without detriment have, in the one case less effective traction in the other less complete fixation. It is then my practice to use a gas-tube frame with a weight extension, the whole being mounted on a "Carshalton" carriage,[1] which allows the patient to share in the social amenities of the hospital

When the disease is quiescent, as shown by the fact that even slight tonic contraction has been completely absent for months, the weight extension, which has been gradually reduced, may be discarded, and the movements which the patient usually tries to make at this stage may be encouraged under careful supervision, no attempt at passive movement, however, should be permitted. The longer this stage is prolonged, the greater is the mobility likely to be, but the position of the limb should be carefully observed and the progress of healing checked by X ray examination When the patient gets up he should wear a short celluloid or leather spica or similar splint and walk on patten and crutches When he is in bed the spica need not be worn and he should be allowed to move the joint if any movement is possible. Especially when the joint is fixed is it important that he should be seen at frequent intervals after the spica has been discarded, lest flexion deformity occur

Secondary Deformities

Secondary deformities of other parts of the body are not uncommon—flat-foot, genu recurvatum, genu valgum and scoliosis Flat-foot, which results from contracture of the tendo Achillis, can be prevented by putting the ankles through a full range of movement each day The genu recurvatum, which is really to a great extent a bend in the upper part of the tibia, can be avoided if the knees are kept a little flexed Genu valgum is sometimes secondary to adduction of the thigh, but not infrequently is the result of traction not having been made in the line of the femur Scoliosis is encouraged if care is not taken to keep the interspinous line at right angles to the long axis of the trunk. It is likely to occur in a severe form, especially in female adolescents, if the hip is ankylosed in a position of adduction with insufficient flexion The best position for ankylosis is moderate flexion, if, with the patient recumbent, the lumbar hollow is obliterated when the limbs are raised 35 degrees, comfortable sitting and standing are both possible If the angle is less, there is an increased tendency to scoliosis, if greater, the patient has to compensate either by excessive lordosis or by bending the knee of the affected limb, which increases the shortening

Adduction persisting to the stage of convalescence requires correction by operation If the joint is not fixed, treatment by tenotomy of the adductors, followed by fixation for several months in plaster, is often sufficient If there is fibrous ankylosis with only moderate deformity Brachett's osteotomy is useful, but when the adduction is marked the deformity is apt to recur owing to instability of the ankylosis In marked adduction, therefore, Lorenz's bifurcation osteotomy is advisable

Abscesses are treated by immobilisation and aspiration, if these fail and the abscess threatens to come to the surface, the thinned area of skin may be excised, the thick tuberculous material in the cavity expressed, and the wound sutured, the bone should never be scraped Some surgeons prefer merely to puncture the pointing abscess with a tenotomy knife Septic tracts should be slit up and allowed to granulate, sequestra if present should be removed, later, the small sinus leading to the joint should be excised, treated with bipp, and sewn up In adults operative measures in the active stage are frequently adopted with a view to obtaining bony ankylosis or pseudarthrosis

Special Articles.

BISMUTH IN THE TREATMENT OF SYPHILIS

By THOMAS ANWYL-DAVIES, M B, B S LOND, M R C S ENG

(*From the Venereal Diseases Department, St Thomas's Hospital, London*)

(*Concluded from p 152*)

Intolerance to Bismuth

IN general the symptoms of bismuth poisoning are similar to those of mercurial poisoning, but the patient recovers sooner from the toxic effects of bismuth The following brief observations on the subject of bismuth toxicology may be of practical interest *Loss of appetite*, accompanied perhaps by vague feelings of indigestion and headache, is the earliest symptom of bismuth poisoning *Loss of weight* is another early sign, and rapid loss of weight of 2 to 4 lb in a few days suggests commencing intolerance *Sleeplessness and depression* are signs of intolerance which may easily be overlooked They are generally accompanied or followed by albuminuria, and indicate suspension of the treatment A *blue line on the gums* is a most valuable sign to the practitioner as it is a guide to the amount of bismuth that can be tolerated, and consequently to the dosage At first a grey line forms round the edge of the gums and this gradually turns to a greyish-blue colour Even when the line becomes definitely blue, provided that stomatitis is absent, the administration of bismuth need not be stopped, but the dosage should be reduced In this way bismuth may be continued for many weeks without ill-effect. On the first sign of stomatitis, however, the injections of bismuth should be stopped, as the action of the drug is cumulative Colonel Harrison [49] has observed that the blue bismuth line on the gums is of more frequent occurrence when using the soluble compounds The bismuth blue line, however, though a useful warning of intolerance, and generally present in the average patient, may be absent in severe bismuth poisoning. The following cases illustrate this important point

Peripheral Neuritis and Albuminuria —Critchley [50] quotes a case of peripheral polyneuritis in a woman of 38 who had kidney disease Five weeks after the first injection of bismuth she had severe pains and exquisite tenderness of the muscles, with loss of strength in all four limbs Diarrhœa and vomiting and the blue line on the gums were absent

The case emphasises the fact that bismuth injections should not be administered when the kidneys are damaged, and that examination of the urine for albuminuria should precede every injection

Bismuth Dermatitis —On one occasion I saw a severe case of exfoliative dermatitis at St Thomas's Hospital venereal department, which was indistinguishable clinically from the well-known arsenical dermatitis, and was due to bismuth alone The patient was a well-nourished tabetic subject who showed no sign of a blue line on the gums

Vincent's Angina —I have had four patients under my care in whom Vincent's angina has developed during the administration of a course of bismuth Stomatitis and the blue line on the gums were not present, and there were no other signs or symptoms of bismuth intolerance, but the Vincent's angina would not respond to the usual methods of treatment until the injections of bismuth were suspended Patients receiving bismuth are more prone to Vincent's angina than usual, which is possibly due to the lowered resistance of the mucous membrane caused by the bismuth excretion in the saliva

Effect on the Kidneys —Clinical experience of the effect of bismuth on the kidneys bears out the conclusions which Brown, Saleeby, and Schamberg [51] obtained experimentally on rabbits that bismuth is a drug of relatively low toxicity They found that 30 mg per kg of insoluble potassium bismuth tartrate in oil (nine times the therapeutic dose in man) could be injected without producing an alteration in the blood chemistry indicative of nephritis or any histological evidence of kidney damage It is on account of this latitude between the therapeutic and the toxic dose that patients rapidly lose any albuminuria when the administration of bismuth is stopped The toxicity for the kidneys seems to correspond with the rate at which the metal is absorbed into the system

Acetyloxyaminophenyl Arsenate of Bismuth.

At the beginning of 1926 Levaditi [52] described a new compound of arsenic and bismuth which had been on trial since 1924—namely, the basic acetyloxyaminophenyl arsenate of bismuth, which contains 40 2 per cent of bismuth and 14 5 per cent of arsenic, and is insoluble in water Suspended in saline it cured experimental syphilis with a dose of 1 5 mg of bismuth per kg of body-weight In an oily suspension the curative dose was 0 041 mg per kg Fournier and Schwartz [53] confirmed these results in the treatment of human syphilis in 20 cases They reported the absence of painful reactions, disappearance of *S pallida* in 24 to 48 hours after the first injection of 2 c cm, rapid cicatrisation of the chancres, and a negative Wassermann reaction in each case after a single series of 12 injections

This drug, bistovol, was tested in the St Thomas's Hospital venereal department, but the above claims were not confirmed It proved very painful, and active spirochætes were found as long as six and seven days after the initial dose When it was found that *S pallida* were present seven days after a single dose of 0 3 g and the negative Wassermann reaction had become strongly positive (+ +) during the same time, stronger doses were injected at shorter intervals In two cases 0 6 g was injected in three days, but the spirochætes were found alive five days after the initial dose, and the Wassermann reaction was positive (+ +) In two other cases 0 75 and 0 9 were given, but the spirochætes were active on the fourth and fifth days respectively.

The Place of Bismuth in the Treatment of Syphilis

It is impossible to judge at present the position that bismuth will ultimately occupy in the treatment of syphilis Under its action *S pallida* disappears rather slowly from the lesion when compared with the rapid effect of arsenobenzol, and experience shows that bismuth and its compounds have not such a powerful spirochæticidal action as arsenobenzol, which can hardly be replaced by bismuth or its compounds in treating cases of early syphilitic infection There seems at present to be some danger of practitioners allowing bismuth to thrust arsenobenzol into the background Such a substitution is not warranted by the evidence Bismuth does not render the patient non-infective so quickly as does arsenobenzol, and its use to the exclusion of arsenobenzol in early cases is likely to be followed by an increase in the prevalence of syphilis, since a greater proportion of cases of syphilis in an early and communicable stage will transmit their disease to others Some at least of the great reduction of cases of syphilis seen for the first time at the treatment centres in England and Wales, from 42,000 in 1920 to 22,000 in 1925, is attributable to the rapidity of action of arsenobenzol, and it would be a great pity if this advantage were to be lost in a wave of enthusiasm for a comparatively new remedy This warning is supported by the fact that in France, where bismuth is more popular and more extensively used than elsewhere, there has been a definite increase in the number of syphilitic cases since 1923, particularly in the large centres such as Paris Prof Josef Jadassohn,[54] speaking at Berlin in November, 1926, on the decline of syphilis in Europe, had collected statistics showing that in both England and France, between 1919 and 1923, there was a decrease of 50 per cent in the number of syphilitic cases, no doubt due to the use of salvarsan During the past four years, however, there had been a recrudescence of syphilis in France, where bismuth was first introduced as an antisyphilitic remedy This was also observed by Dr E Jeanselme,[55] of the Hôpital St Louis, who found that there was an increase of 20 per cent in the number of cases recently infected with syphilis in Paris, the figures having risen from 1955 in 1921 to 2445 in 1925 As the author stated, this may be due in part to the enormous immigration of foreign workmen into the large manufacturing centres in that country, but the chief reason advanced by Jeanselme is the indiscriminate substitution of bismuth compounds for salvarsan The view is held by many French doctors that bismuth is more active therapeutically than arsenobenzol

If not a substitute for arsenic, can bismuth replace mercury? This is a difficult question which it is impossible to answer conclusively, considering our present knowledge The experimental evidence obtained by the action of bismuth on syphilis in the rabbit is in favour of that drug, but the clinical results and the pathological findings in man have not been so successful Raiziss and Severac[56] consider that bismuth compounds are powerful enough to cause complete eradication of infection in experimental syphilis in the rabbit, but that salvarsan has a higher chemotherapeutic index than bismuth, although this is distinctly superior to mercury Workers disagree concerning the effect of bismuth on the Wassermann reaction It does not seem to have any marked effect in changing a positive to a negative result in the serum of cases of late syphilis or in Wassermann-fast subjects, but there is general agreement that clinically the tertiary lesions, especially those in the mouth, and the symptoms of neurosyphilis, excluding general paralysis, respond rather well to the administration of bismuth On the other hand, certain observers have reported that poor results occur in some cases, there being apparently little or no therapeutic effect The more favourable result of the Wassermann test in the series of mercury-treated cases when compared with those treated with bismuth suggests that mercury is more active therapeutically than bismuth, since as our knowledge stands at present the blood test results are the best criterion of the effect of treatment.

Indications for Preference of Bismuth to Mercury

There are certain times when bismuth is the remedy of choice It is not so toxic, and can be more easily tolerated than mercury in nephritic cases In cases of jaundice due to arsenical poisoning, bismuth can be given without causing the patient any inconvenience, while mercury, owing to its greater toxicity, is not so satisfactory In advanced organic disease bismuth is often tolerated when arsenic and mercury would be inadvisable Occasionally, in cases of late syphilis which have been inadequately treated with mercury in which the spirochætes have possibly become mercury-resistant, good results often follow a change to bismuth

There is only one practical contraindication to bismuth and that is stomatitis, which can be prevented with suitable care If disinfection of the mouth and aperients fail to remove it, injections of sodium thiosulphate, 0 45 to 0 9 g, should be given daily. This does not seem to be so effective intravenously as when given by the deep subcutaneous route Sodium thiosulphate causes no reaction, and any pyrexia after its use is not due to the drug itself

The therapeutic and toxic actions of mercury are always proportional to the amount of metallic mercury present The ratio of the curative to the toxic dose is high At the moment all efforts to increase the margin between the therapeutic and the toxic dose of mercurial preparations have failed, and more often than in the case of bismuth the syphilologist may be baulked of his result by the patient's intolerance of the remedy

There are, however, arguments in favour of alternate courses of mercury and bismuth Prof E Glynn, Dr R E Roberts, and Dr Phoebe M Bigland[57] (Medical Research Council Report, No 107, November, 1926, on the effect of treatment on the Wassermann reaction) express the conviction that a serological relapse of the patient, the Wassermann reaction becoming again positive, indicates renewed activity of *S pallida* They state that strains of *S pallida* resistant to mercury may be produced by the prolonged and insufficient administration of this drug They consider that mercury attacks the spirochætes when circulating in the blood, but is unable to reach the inaccessible residual spirochætes which, in the later stages of syphilis, become protected in fibrotic lesions, indurated lymph glands, testis, and spleen If the views of these writers are correct, they indicate the advisability of varying the remedy, giving in one course mercury, in another bismuth, and so on, a plan which seems to be favoured by a number of American syphilologists

Probably bismuth, like mercury, is capable of producing bismuth-resistant spirochætes, particularly if the dosage given is insufficient to destroy them Giemsa[58] found that spirochætes transferred from one rabbit to another developed resistance to inadequate doses of sodium tribismuthyl tartrate Glynn, Roberts, and Bigland[57] recommend the use of salvarsan for the prevention of Wassermann relapses and the destruction of residual spirochætes, as they consider that arsenobenzol does not produce spirochætes resistant to this drug. I am sceptical of this, and am inclined to think that arsenobenzol, mercury, and bismuth compounds may each produce resistant spirochætes, especially when prolonged hypotherapeutic doses are administered In support of this view Klauder[59] reported that he had produced arsenic-resistant strains of *S pallida* in rabbits by giving them small subcurative doses of arsenobenzol, and inoculating the strain through several animals

Stokes,[60] of Philadelphia, considers that half the mercury in all courses of treatment can be replaced by bismuth with advantage, and recommends alternate courses with mercury. He prefers to begin with a soluble mercurial salt, however, in cases of early neurosyphilis, because of its quicker direct action on *S. pallida* instead of the possibly only inhibitory action of bismuth Dennie[61] believes that recurrent syphilis should be treated by salvarsan with mercury administered to the limit of tolerance and alternated by courses of bismuth

All these are arguments for the administration of arsenobenzol at the same time as mercury or bismuth in preference to the separate use of these drugs Mercury and bismuth, however, should not be exhibited together as they are eliminated by the same routes, and their toxic effects are similar and additive

I would like to sound a note of warning against the indiscriminate use of the bismuth compounds if the best therapeutic results are to be obtained Sufficient time has not elapsed for us to decide whether bismuth or mercury is more effective, but the results after four years of bismuth therapy do not warrant the wholesale adoption of bismuth to the extinction of mercury In spite of the fact that bismuth has been enthusiastically adopted, thoughtful workers will question the advisability of discarding mercury at this stage of our knowledge, for the ascendancy of bismuth over mercury in the cure of syphilis has not been established, although the easy convenience of the painless administration of an insoluble bismuth compound is an important factor in dealing with frail humanity

In general the results of workers in this country have not confirmed the findings of Levaditi and his co workers in France, and although bismuth is convenient to administer, it seems doubtful if it will succeed in replacing mercury entirely in the chemotherapy of syphilis

Conclusions

1. Bismuth and its compounds have a definite use in the treatment of syphilis 2 The soluble compounds are painful and more toxic than the insoluble drugs, which are painless 3 Metallic bismuth is the least toxic of these preparations 4. The most satisfactory method of administration is by the deep subcutaneous route 5 Severe bismuth poisoning may occur in spite of the absence of the blue line on the gums

6 Bismuth is capable of eliciting the Jarisch-Herxheimer reaction. 7 Tertiary lesions of the mouth and tongue, and the symptoms of tabes, respond particularly well to bismuth therapy 8 Bismuth may not be so powerful as mercury, but it is more convenient to use 9 Bismuth and arsenobenzol have not such a strong effect on the Wassermann reaction as arsenobenzol and mercury. 10 Bismuth is valuable in cases of nephritis, jaundice, and advanced organic disease, where mercury and arsenic may not be suitable, and in late syphilitic cases which have become resistant to arsenic and mercury. 11 The evidence is in favour of bismuth, arsenic, and mercury, being all capable of producing resistant spirochætes when administered in subtherapeutic doses 12 Bismuth is not an efficient substitute for arsenobenzol 13. Recent experiments by Kolle and Evers suggest that bismuth may have an *inhibitory* action rather than a curative effect, and at present our knowledge does not warrant the wholesale adoption of bismuth instead of mercury 14 It is not established that bismuth is more effective than mercury in the permanent cure of syphilis, and it may be found that the curative value of mercury is higher than that of bismuth

The writer is indebted to Colonel Harrison, director of the St Thomas's Hospital Venereal Diseases Department, for permission to quote the results obtained in the clinic, and for valuable assistance in preparing this paper

THE INCIDENCE OF CANCER IN MONASTIC COMMUNITIES

THE incidence of cancer upon members of certain religious orders has been the subject of an elaborate statistical investigation[1] undertaken by Dr S Monckton Copeman, F.R S, and Prof Major Greenwood under the auspices of the Departmental Committee on Cancer of the Ministry of Health Sir George Newman remarks in a prefatory note that though the results of the inquiry are negative, they are well worth publishing, not only for their scientific value. but as an indication of the kind of proofs that have to be sought before the various popular dietetic theories of cancer can be accepted

The authors of the monograph point out that, of the many thousands of pages devoted to speculations on the ætiology of cancer, a by no means negligible proportion are devoted to the indictment of general or particular dietetic habits Certain English medical men, whose names deservedly carry great weight in different departments of medicine and surgery. have suggested that rich, abundant food, particularly meat, contributes to the production of cancer; that intestinal stasis conditioned by the diet of civilised mankind is the most important ætiological factor of malignant disease; and that the increased use of preservatives in the food industries has a bearing upon the increase of mortality from cancer.

Correlation and Causal Relation

The objection in principle to most of the arguments on these lines used by various writers is, they contend, that a correlation in time or place between cancer mortality and some other variable is tacitly interpreted as being equivalent to a causal relation. provided such an assumption is not patently absurd Nobody, of course argues that the increase during the last quarter of a century of the Socialist Party has been an ætiological factor of increasing mortality from cancer, because no rational person can imagine any direct relation of cause and effect between the two variables But if we were to substitute for Socialist Party, consumption of meat, of margarine. or of tinned foods, many intelligent people would accept the argument as valid, because they can imagine ways in which increased consumption of animal protein, of vitamin-poor fat, or of antiseptics *might* prejudice normal cellular metabolism. The *statistical* argument in one case is precisely as good as in the other, carrying us no further than the proposition that the statistics are compatible with the truth of the assertion that the growth of the Socialist Party, of the consumption of meat, of margarine, or of American canned goods, *may* be a factor of increasing cancer mortality. An English writer who seriously

attempted to meet these criticisms was the late Rollo Russell, who argued that if the constituents of a diet be really an ætiological factor, then we should try to study the cancer mortality of persons living under conditions which, *except* in respect of diet, are comparable with those experienced by populations wherein cancer is a large and measurable factor of mortality. In his work, published in 1912, Russell gave statistics of seven Cistercian and Benedictine Monasteries, in which the total number of the votaries extending over a period of about 26 years was 120; during this time only one death from cancer was recorded, this being attributed by him to the exceptional habitual use of a strong irritant (pepper).

These observations of Russell were the starting-point of the present inquiry. The dietetic habits of the Carthusians, Benedictines, Cistercians, Carmelites, and Dominicans were studied, the two last named not being enclosed orders, and both English and Belgian data were analysed. The next step was to attempt to obtain an accurate record of the ages and lengths of time under observation of the persons whose risk of dying of cancer it was sought to measure, together with the certified causes of death of those who died.

The Ecclesiastical authorities of five religious houses in England, and one in Belgium, and the staff of the General Register Office furnished particulars from which life tables could be compiled, the standard of expected death being taken from the tables of the British Official Life Annuity Experience (1893).

Inferences Drawn

These tables are set out in the report, the data are analysed, and a few inferences drawn. A *certain* inference is that no statements as to causes of death, even when made in absolute good faith, by persons long resident in the communities should be accepted without verification. Thus among the English Carthusians and Cistercians (males) visited by one of the authors, *one* death only was known by the authorities to have been due to cancer. Investigation of the death registers raised the number of definitely certified deaths from cancer to *seven* and disclosed four others which might have been due to cancer.

What reliance can be placed on hearsay statements respecting mortality from cancer amongst, say, aborigines, the reader may judge in the light of this investigation of well-kept records. An equally certain inference is that, upon the evidence, we cannot say that a prima-facie case has been made out in favour of the proposition that any of the Orders are less liable to cancer than their lay contemporaries in the world.

A study of the general statistics of Cistercian communities throughout the world confirmed the conclusion reached that cancer does occur as a fatal disease in Cistercian Houses everywhere, whether the real incidence is high or low cannot be learned. The necessary data do not exist.

Incidence of Fatal Cancer upon Inmates of Prisons and Mental Hospitals

The low rates of mortality from cancer recorded in prisons and mental hospitals has been the subject of comment, and the authors append some critical observations on this point. The inmates of prisons and mental hospitals have only one point of resemblance to members of religious orders—viz., that they reside in institutions and receive a diet less varied and less rich in proteins and fats of animal origin than the general population. The most valuable analysis of prison data is to be found in a monograph on the English Convict, by the late Charles Goring, who came to the conclusion that cancer was less prevalent amongst convicts than in the general male population. The authors of this investigation, after studying Goring's figures, agree with him that the fatal incidence of cancer on convicts appears to be lower than on the general population of like age, but, as it was impossible to examine the death certificates or to determine the precise exposure to risk (as they had been able to do for the religious orders), and as they found in the latter case that first impressions were not confirmed by a closer examination, they do not feel entitled to draw any stronger conclusion from the evidence available than a verdict of not proven. An analysis of the data accumulated in the 19 years which have elapsed since the end of the period covered by Goring will be carried out when occasion permits.

As to mental hospitals, attention has been directed officially more than once (e.g., in the Sixty-fifth Annual Report of Commissioners in Lunacy, p. 26, and Tenth Annual Report of the Board of Control, p. 34) to the fact that the proportional mortality from cancer in the mental hospital population is much less than in the general population.

After making various allowances, the authors conclude that there is no important difference between the rate of cancer mortality upon inmates of mental hospitals and that upon the general population. But the fact that, *relatively to other causes of death*, cancer is less frequent in mental hospitals than outside them, has led some to suggest that there may be special factors militating against the prevalence of cancer. One such factor is the huge force of mortality exerted by causes either peculiar to the insane, such as general paralysis or notoriously frequent amongst them, such as tuberculosis. But it may still be urged that since, judged by mortality-rates from diseases *not* peculiar to the insane the inmates are "bad" lives, there is at least a relative immunity to cancer which needs explanation. This argument, however, rests on the tacit assumption that the fatal incidence of cancer varies with the general resistance of the body. This is a plausible assumption but it is not easy to justify. The analyses made for the Cancer Commission of the League of Nations, dealing with the incidence of different forms of cancer upon women (Data of England and Wales 1911–20), led to the conclusion that those subdivisions of the country with high (or low) rates of mortality from cancer of the uterus or breast did not, on the average, have high (or low) rates of mortality from other diseases. This argument is, of course, not conclusive, and, while drawing no inference, the authors consider it proper to call attention to the fact that two types of institutional population, convicts and the insane, while differing widely in respect of general mortality—the former having a rate somewhat superior to and the latter enormously worse than the general rate—do have this in common, that *both* show either an absolutely or relatively low rate of mortality from malignant disease.

Conclusion

The analysis of the data supplied by monastic communities conclusively proves that fatal cancer occurs in populations abstaining from flesh food, and lends no real support to the contention that among such populations the relative incidence of cancer is low.

A tribute is paid by the authors to Cardinal Bourne, Monsignor Jackman, and to the many conventual Superiors who have made the analysis possible, often at the cost of very considerable labour in searching records and entering particulars upon cards. Although, in a sense, the results are inconclusive, the labour has not been in vain. A perusal of this report will convince most impartial persons that no scientific value whatever attaches to assertions, supported merely by the vague pseudo-statistical evidence which is customarily cited, respecting the rôles of certain articles of common consumption in the genesis of cancer. There is a too general impression that it is the duty of scientific men, particularly those in the public service, to try out any and every suggestion of this kind. As the present report abundantly proves, the trying out of any such suggestion is a most laborious business, not merely for the investigator, but for the persons called upon to supply information.

WELSH NATIONAL SCHOOL OF MEDICINE

THE QUESTION OF A CHARTER

ON Jan 14th a special meeting of the Court of the University of Wales was summoned at Shrewsbury, for the express purpose of receiving and confirming a draft Charter incorporating the Welsh National School of Medicine as an independent school of the University This Charter had been prepared by the University Council in accordance with a decision reached at a previous meeting of the Court held in October, 1925 The adoption of the draft Charter was proposed by Mr W N Bruce and seconded by Alderman William George However, an amendment by Mr A H. Trow, B Sc , Principal of the University College of South Wales and Monmouthshire, in favour of the reference of the proposals back to the University Council for further consideration and conference with the College was carried by 53 votes to 48 The amendment was supported by the opinion of Counsel, Mr Alexander Grant, K C , whose views on certain legal points appear to have had considerable influence on the voting In answer to various questions put to him by the University College of South Wales and Monmouthshire, he gave the opinion that the scheme suggested by the University Council was beyond the powers of the University as conferred by its present Charter or by the suggested altered Charter, that the proposed scheme was a grave infringement of the rights of the College to which the school had hitherto been attached, and that an Act of Parliament would be required if property now vested in the University College of South Wales and Monmouthshire were to be transferred to the new school. Dr Rocyn-Jones, seconding the amendment, suggested that the adoption of the Council's proposals would hasten the day when the Federal University of Wales would become extinct through the constituent Colleges attaining University rank Before the voting was taken a letter was read by Lord Kenyon, Pro-Chancellor of the University, from the Privy Council in which the early lodgement of the draft Charter and the petition was pressed for since the consideration of the documents would inevitably take a long time This letter contained no suggestion that the scheme for incorporating the school as an independent school of the University was not legally possible, but the Court did not appear to be convinced by this letter nor by the Pro-Chancellor's statement that the University Council had taken the advice of their own Counsel, Mr Tyldesley Jones, as to the changes in the University Charter necessary to enable the scheme to be carried out, and that these were embodied in the papers before the Court The General Medical Council have made it clear that they favour the establishment of a complete national medical school by giving notice of their intention to oppose any Charter which does not provide ,for the inclusion of anatomy and physiology

In view of the abortive result of many previous attempts to reach agreement between the Councils of the University and of the College, it is difficult to foresee a happier result from their resumption It is certainly unfortunate that a further six months' delay in taking even the first step towards establishing the status of this school seems inevitable, for its unsettled position must be prejudicial to its welfare

BLACKBURN ROYAL INFIRMARY —Blackburn War Memorial is to take the form of a new wing to the Royal Infirmary, to be put up at an estimated cost of £80 000 Of this sum £20,000 is still required

EXTENSION OF STOCKPORT INFIRMARY —A new orthopædic department of the Stockport Infirmary was opened by Lady Sheffield on Jan 13th The building has been built and equipped at a cost of £9000 and provides massage, electrical and artificial sunlight treatment There is also a gymnasium for Swedish remedial exercises

MEDICINE AND THE LAW

Spinner's Cancer on the Face

ON Jan 13th at the Oldham County Court Judge Spencer Hogg had before him the first claim by a mule-spinner for compensation for cancer of the face The case was taken under the industrial disease section, and compensation at the rate of £1 8*s* 8*d* per week was claimed The plaintiff said that he had been a spinner for 20 years and had worked at the defendants' mills for 11 years At the beginning of 1925 he had noticed a small wart about an inch from his left eye At the time he had thought little of it but the wart had grown larger, and when he went to see his doctor he was sent to the infirmary After an operation, performed in July last, the certifying surgeon had given a certificate stating that the plaintiff was suffering from epitheliomatous ulceration caused by mineral oil Dr A C Sturrock said that the case was one of epithelioma of the face, and might have been caused by small quantities of mineral oil being rubbed into the skin over a long period He had seen only one previous case of cancer of the face in a spinner, but had seen the condition in people who were not spinners For the defence Dr Thomas Watts, certifying factory surgeon for the Ashton and Hyde District, said he had never come across such a case in a spinner, and had had none reported to him After other evidence had been heard it was contended for the defence that the disease could have arisen from some other cause and even naturally The Judge said that his duty was very limited owing to the wording of the certificate which had been accepted Any common-sense man, having regard to the daily life of the spinner and the chances of contact with oil, would realise that it was obvious that the man had got the disease through contact with mineral oil over a large number of years He gave an award for the amount claimed, the payment to date from December, 1925

Unusual Claim for Compensation

Judge Leigh sitting at Manchester County Court, on Jan 10th awarded £300 and costs to the widow of a solicitor's clerk who admittedly suffering from weakness of the heart, had hurried after one of his employers to catch a train, and had fallen dead on the slope to the platform as his employer was purchasing tickets for the journey The actual defendant of the action was an assurance company The dead man, aged 54, was a clerk engaged almost exclusively on cases under the Workmen's Compensation Act On July 29th he attended a prolonged inquest at Hawarden Bridge Iron Works, and immediately afterwards hurried after his employer to catch a train At the inquest the verdict was one of death from natural causes Two medical men had advised the deceased that although there was degeneration of the heart muscle, he might follow his ordinary occupation if he avoided excessive effort or strain The defence contended that death was due to disease and not to accident, and that it had really occurred on the completion of his duties The Judge said it was quite clear that whilst the deceased had suffered for some time from myocardial degeneration, it was also plain that his disease had not been progressive The immediate cause of death was the excessive exertion against which he had been warned, and this exertion had been brought about by following his employer in the course of his employment, the " accident " in this case being the necessity of rushing to catch the train

Imported " New Laid " Eggs

A firm carrying on business in Farringdon-road. E C , was fined £2 lately for offering for sale " new laid eggs " without including in the description the word " imported " or words disclosing the country of origin from which the eggs had been imported Two other defendants were fined 40s for the same offence The " new laid eggs " came from Australia The prosecution (by the Middlesex County Council) attempted to meet these criticisms was the late Rollo Russell, who argued that if the constituents of a diet be really an ætiological factor, then we should try to study the cancer mortality of persons living under conditions which, *except* in respect of diet, are comparable with those experienced by populations wherein cancer is a large and measurable factor of mortality In his work, published in 1912, Russell gave statistics of seven Cistercian and Benedictine Monasteries, in which the total number of the votaries extending over a period of about 26 years was 120, during this time only one death from cancer was recorded, this being attributed by him to the exceptional habitual use of a strong irritant (pepper)

These observations of Russell were the starting-point of the present inquiry. The dietetic habits of the Carthusians, Benedictines, Cistercians, Carmelites, and Dominicans were studied, the two last named not being enclosed orders, and both English and Belgian data were analysed The next step was to attempt to obtain an accurate record of the ages and lengths of time under observation of the persons whose risk of dying of cancer it was sought to measure together with the certified causes of death of those who died

The Ecclesiastical authorities of five religious houses in England and one in Belgium, and the staff of the General Register Office furnished particulars from which life tables could be compiled, the standard of expected death being taken from the tables of the British Official Life Annuity Experience (1893)

Inferences Drawn

These tables are set out in the report, the data are analysed, and a few inferences drawn A *certain* inference is that no statements as to causes of death, even when made in absolute good faith, by persons long resident in the communities should be accepted without verification Thus among the English Carthusians and Cistercians (males) visited by one of the authors, *one* death only was known by the authorities to have been due to cancer Investigation of the death registers raised the number of definitely certified deaths from cancer to *seven* and disclosed four others which might have been due to cancer.

What reliance can be placed on hearsay statements respecting mortality from cancer amongst, say, aborigines, the reader may judge in the light of this investigation of well-kept records An equally certain inference is that, upon the evidence, we cannot say that a prima-facie case has been made out in favour of the proposition that any of the Orders are less liable to cancer than their lay contemporaries in the world

A study of the general statistics of Cistercian communities throughout the world confirmed the conclusion reached that cancer does occur as a fatal disease in Cistercian Houses everywhere, whether the real incidence is high or low cannot be learned The necessary data do not exist

Incidence of Fatal Cancer upon Inmates of Prisons and Mental Hospitals

The low rates of mortality from cancer recorded in prisons and mental hospitals has been the subject of comment, and the authors append some critical observations on this point The inmates of prisons and mental hospitals have only one point of resemblance to members of religious orders—viz , that they reside in institutions and receive a diet less varied and less rich in proteins and fats of animal origin than the general population The most valuable analysis of prison data is to be found in a monograph on the English Convict, by the late Charles Goring, who came to the conclusion that cancer was less prevalent amongst convicts than in the general male population The authors of this investigation, after studying Goring's figures, agree with him that the fatal incidence of cancer on convicts appears to be lower than on the general population of like age, but, as it was impossible to examine the death certificates or to determine the precise exposure to risk (as they had been able to do for the religious orders), and as they found in the latter case that first impressions were not confirmed by a closer examination, they do not feel entitled to draw any stronger conclusion from the evidence available than a verdict of not proven An analysis of the data accumulated in the 19 years which have elapsed since the end of the period covered by Goring will be carried out when occasion permits

As to mental hospitals, attention has been directed officially more than once (e g , in the Sixty fifth Annual Report of Commissioners in Lunacy, p 26, and Tenth Annual Report of the Board of Control, p 34) to the fact that the proportional mortality from cancer in the mental hospital population is much less than in the general population

After making various allowances, the authors conclude that there is no important difference between the rate of cancer mortality upon inmates of mental hospitals and that upon the general population But the fact that, *relatively to other causes of death* cancer is less frequent in mental hospitals than outside them, has led some to suggest that there may be special factors militating against the prevalence of cancer One such factor is the huge force of mortality exerted by causes either peculiar to the insane, such as general paralysis, or notoriously frequent amongst them, such as tuberculosis But it may still be urged that since, judged by mortality-rates from diseases *not* peculiar to the insane the inmates are "bad" lives, there is at least a relative immunity to cancer which needs explanation This argument, however, rests on the tacit assumption that the fatal incidence of cancer varies with the general resistance of the body This is a plausible assumption, but it is not easy to justify The analyses made for the Cancer Commission of the League of Nations, dealing with the incidence of different forms of cancer upon women (Data of England and Wales 1911–20), led to the conclusion that those subdivisions of the country with high (or low) rates of mortality from cancer of the uterus or breast did not, on the average, have high (or low) rates of mortality from other diseases This argument is, of course, not conclusive, and, while drawing no inference, the authors consider it proper to call attention to the fact that two types of institutional population, convicts and the insane, while differing widely in respect of general mortality—the former having a rate somewhat superior to and the latter enormously worse than the general rate—do have this in common, that *both* show either an absolutely or relatively low rate of mortality from malignant disease

Conclusion

The analysis of the data supplied by monastic communities conclusively proves that fatal cancer occurs in populations abstaining from flesh food, and lends no real support to the contention that among such populations the relative incidence of cancer is low

A tribute is paid by the authors to Cardinal Bourne Monsignor Jackman, and to the many conventual Superiors who have made the analysis possible, often at the cost of very considerable labour in searching records and entering particulars upon cards Although, in a sense, the results are inconclusive, the labour has not been in vain A perusal of this report will convince most impartial persons that no scientific value whatever attaches to assertions, supported merely by the vague pseudo-statistical evidence which is customarily cited, respecting the rôles of certain articles of common consumption in the genesis of cancer There is a too general impression that it is the duty of scientific men, particularly those in the public service, to try out any and every suggestion of this kind As the present report abundantly proves, the trying out of any such suggestion is a most laborious business, not merely for the investigator, but for the persons called upon to supply information

PARIS

(FROM OUR OWN CORRESPONDENTS)

Diabetes Refractory to Treatment with Insulin

It is often said that in certain cases of diabetes insulin proves useless In a communication recently made to the Académie de Médecine Prof Marcel Labbe analyses the types of case in which it has no effect, and finds that they include glycosuria due to abnormal function of the kidneys, liver, pituitary, and thyroid diabetes of very mild type which need not be treated by insulin, and true diabetes aggravated by infection general anæsthesia, or some other constitutional disturbance In most cases of apparent resistance to treatment it is questionable he says whether the dietetic régime is properly carried out by the patient in many others the dose of insulin given is insufficient, especially where the condition is made worse by infection Insulin is a powerful drug having a physiological action which is certain, although not yet been shown to be curative According to Prof Labbé insulin is always effective when properly used and there is no such thing as a form of true diabetes refractory to its action

Splenectomy for Purpura Hæmorrhagica

Two years ago a girl of 9 developed serious purpura with repeated hæmorrhages Her condition grew worse in spite of all treatment and there were only two remissions, one of them after injection of maternal whole blood and the other after radiotherapy. Neither proved more than transitory and death appeared imminent when Lafourcade, of Bayonne performed splenectomy The result exceeded all hopes and was evidently due to the operation alone, for the child has had no other treatment since it was done This case may be added to the few already published—one in France and a score abroad —in which splenectomy has cured recurrent hæmorrhagic purpura

Malaria in Two French Districts

In the Department of the Ain there is a district called Les Dombes which until the end of last century was always very marshy The construction of a railway made it necessary to drain a large part of it, and little by little the country has been rendered prosperous Prof Marchoux, of the Pasteur Institute, was sent to study malaria in this district, and states that although there are always many ponds and millions of anopheles malaria has disappeared The sporadic cases which are met with do not lead to infection around them He has made a similar study at La Camargue, which is in the Rhone delta and is an island of very fertile soil Here the proprietors have become wealthy and recruit their labour amongst foreigners—Italians, Spanish, Serbs—who work under contract, are badly lodged and poorly fed, and labour without rest Malaria persists everywhere from which it may be concluded that the malarial incidence does not vary as the number of anopheles These are mainly parasitic to animals and abound when animals are found within easy reach When, on the other hand, man is their only prey, they multiply with difficulty but infect themselves with certainty and are a sure source of infection to people living in the district

Asthma and Ultra-violet Light

Before the Société de Thérapeutique, Saidman has given particulars of the technique useful in treating asthma by irradiation The polymetallic arc, he says is satisfactory in 80 per cent of cases, with the same doses the mercury-vapour lamp gives only 46 per cent of successes. An intense source of light should be used and it should cause erythema The curative properties seem to be due to the associated effects of the ultra-violet and infra-red rays, of the gas released by the arc, and of the ionised air Cure is much more rapid in children, and sometimes when there is no enlargement of tracheobronchial lymph glands, the attacks disappear after a single sitting In adults the effects are less consistent and the treatment longer but relapse may be prevented by periodical treatment.

Influenza in Paris

Influenza was exceedingly prevalent at Paris during December, when it caused 180 deaths per day Between Dec 11th and 20th, when the epidemic reached its peak the daily average mortality was 198, but since then it has rapidly subsided Admissions to hospital have fallen from 698 on Dec 17th to 193 on Jan 8th Favourable weather has caused a similar decrease in influenza at Montpellier

Among the more important meetings of the present year will be an exhibition of medical appliances and therapeutic products, at Lyons in March; the Sixth National Tuberculosis Congress, at Lyons, from April 11th to 14th, the Annual International Neurological Assembly, from May 30th to June 1st, the French Congress of Alienists and Neurologists from August 1st to 6th, the Fifth French Pædiatric Congress, at Lausanne during September and October, the Thirty-sixth Surgical Congress, from October 3rd to 8th, the French Medical Congress from October 10th to 11th, and the Congress of Hygiene, at the Pasteur Institute, in October

The Association for the Development of Medical Relations is gaining an increasing influence abroad. It is now assisting in the organisation of a medical library at Warsaw, and receives large groups of visitors from Poland, the United States and elsewhere a special reception was recently given in honour of Prof Clemens von Pirquet, of Vienna The Association has sent physicians and surgeons to Serbia, Egypt, the Near East, and Colombia and is ready to provide information about French post-graduate courses in medicine surgery, and obstetrics

The total number of medical diplomas awarded by French universities during 1925–26 was 1242, of which 631 were given at Paris Of these diplomas 1132 conferred the right to practise medicine in France and the French colonies, whilst the rest provided only the university grade without State rights After Paris, the largest numbers of degrees were awarded by the universities of Lyons (166), Bordeaux (127), and Montpellier (113)

FORMER PATIENTS ENDOW A BED.—Some months ago an Old Patients' Association was formed for the upkeep of one or more beds in the Salford Royal Hospital Members promise to give a minimum subscription of half a crown a year and the first bed has now been endowed was presumably undertaken under Article 8 of the Sale of Food Order, 1921, which runs as follows

"A person shall not sell or offer or expose for sale, whether by wholesale or retail, as fresh eggs or new laid eggs or under any description of which the words 'fresh' or 'new laid' form part, any eggs which have been imported into the United Kingdom unless the description also includes the word 'imported' or a word or words disclosing the country of origin"

It is entirely proper that Parliament should provide that eggs which have travelled from Australia should not be sold in London as "new laid" without qualification, and municipal officers are rightly vigilant in enforcing the law But the law itself might now be recast with advantage The Sale of Food Order of 1921 is a relic of food control days Only two of its six parts survive, and these are kept alive somewhat precariously by an extension of the Ministry of Food (Continuance) Act under the Expiring Laws Continuance Acts of the past few years Part I. of the Sale of Food Order relates to the sale of bread by weight, it seems to be superseded prospectively by the somewhat similar provisions of Section 6 of the recently passed Sale of Food (Weights and Measures) Act which comes into force next July. Presumably Part I will then be revoked Part III deals with the labelling of imported produce (meat, bacon, ham, lard and eggs) Its contents do not appear to be replaced by the recent Merchandise Marks Act which requires imported goods to bear an "indication of origin" Part III, therefore, can hardly be revoked until Parliament passes fresh legislation to take its place It is advisable that this fresh legislation should not be too long delayed Restrictions which recall D O R A and the war period are unpopular There is consequently a more marked tendency to evade them, and a greater disinclination on the part of magistrates to inflict serious penalties It is unsatisfactory that considerations of this nature should be allowed any foothold in matters relating to public health

Milk Bottles Filled in Street

Under this heading we reported on Dec 18th, 1926 (p 1287), that the Brighton justices had fined a milk roundsman and his employer because the roundsman was seen in the street filling bottles from a can and closing them with caps taken from his pocket The offence was observed by Dr Duncan Forbes, medical officer of health for Brighton and the fine was inflicted under the Milk and Dairies Order, 1926 An appeal, however, was entered and was heard at the Brighton Quarter Sessions on Jan 3rd, when the employer stated that he had not been represented at the first hearing because he thought that the roundsman's evidence would have refuted the charge He had read the regulations to those working at his registered premises and had no idea that any bottling was done outside these premises The Recorder decided that it had not been within the employer's knowledge that the roundsman had done what he did, and quashed the previous conviction, without, however, allowing the appellant's costs

---

BRITISH PATHOLOGISTS' ASSOCIATION.

A MEETING attended by some 40 medical men and women, attached as pathologists to various London and provincial hospitals was held at the London School of Medicine for Women on Jan 7th, for the purpose of considering the formation of a society to represent the interests of those engaged in the practice of pathology in this country Dr S C Dyke, pathologist to the Wolverhampton and Staffordshire Hospital, took the chair

On the motion of Dr A. G Shera, of Eastbourne, seconded by Dr W Grace, of Chester, it was decided to form such a society, and on the motion of Dr A F Sladden, of Swansea, seconded by Dr A Renshaw, of Manchester it was decided that the name of the society should be the British Pathologists' Association The aims of the society were laid down as being 'to develop the application of pathology in relation to medicine and to protect the interests of those engaged in its study and practice" It was decided that membership should be open to all registered medical practitioners engaged in the study and practice of pathology The annual fee for membership was set at one guinea, and it was decided that there should be no entrance fee All those present at the meeting were made eligible for membership; future candidates will require nomination by two members The following officers of the association were appointed President, Dr C Powell White (Victoria University, Manchester), chairman, Dr. J G Greenfield (London), secretary, Dr S C Dyke (Wolverhampton), treasurer, Dr A Renshaw (Manchester), members of council Dr E Wordley (Plymouth); Dr G Hadfield (Bristol), Dr A G Shera (Eastbourne), Dr. A F Sladden (Swansea), Dr W Grace (Chester), and Dr R V Solly (Exeter)

IRELAND

(FROM OUR OWN CORRESPONDENT)

Precautions against Small-pox in the Irish Free State

THE Department of Local Government and Public Health has issued a circular letter to all health authorities throughout the Irish Free State drawing their attention to the outbreak of small pox in England and to the necessity for precautions against its spread to Ireland The Secretary of the Department reminds the health authorities of the terrible visitations of small-pox in 1871 and *1878*, and the varied and serious complications which accompanied the disease He points out that in addition to the danger to health and loss of life, an outbreak would prove a serious menace to the prosperity of the food and export trade, and would affect the tourist traffic adversely It is of vital importance that steps should be taken by vaccination and re-vaccination, to render the population immune The Minister, therefore, requests the local authorities without delay to take all necessary steps to compel defaulters to comply with the law and to bring to the notice of all those desiring re-vaccination that full facilities for this purpose are at their disposal

A Surgeon's Action for Fees

An action was heard last week in Dublin before Mr Justice Hanna sitting without a jury, in which Mr Denis Kennedy surgeon to St Vincent's Hospital claimed £1468 from the executors of a patient The claim was made for services rendered, but the defendants said that the services alleged had not been given, that the fees charged were not agreed fees, and that they were exorbitant and unfair While denying any liability, the defendants brought into court the sum of £526, which they said was sufficient to satisfy plaintiff's claim

Giving evidence of the operations performed, Mr Kennedy said that he had been in attendance on the patient for nearly two years He never sent in his account as she never asked for it, but she had said that his fees would be all right Mr J S McArdle, senior surgeon to St Vincent's Hospital, was examined and said that the usual fee for operations of the kind mentioned was 100 guineas, but it was not the maximum fee His minimum fee for such an operation was 50 guineas Mr R C B Maunsell Past President of the Royal College of Surgeons in Ireland, said that the fees charged were good full fees, but certainly not excessive Asked if it was not usual to send a bill before the patient died, he said that in some cases it was kind not to do so In giving judgment for plaintiff for the sum of £680 and costs, Mr Justice Hanna said that the executors had been right to bring the case into court when faced with a charge which they thought excessive. The amount might have been left to some eminent surgeon, but it might be difficult to get a medical man to decide as between a colleague and an outsider

EDWIN STEPHEN PASMORE, M D., M R C P, LOND., D Sc, LL D.

THE death of Dr Pasmore at the age of 62 years is a heavy loss to the county borough of Croydon where he had been in charge of the mental hospital since its foundation a quarter of a century ago

Edwin Stephen Pasmore was the son of Capt John Pasmore, and was born at Falmouth in 1864 He studied at the Universities of London, Paris and Brussels, taking his medical degree from University College, London, in 1890 and his doctorate in the following year After holding house appointments at University College Hospital and Ramsgate he became clinical assistant to Sir William Gowers at Queen Square and from that time onwards was deeply interested in mental welfare and took a leading part in furthering the public mental hospital movement in this country In 1893 he was appointed pathologist first to Banstead—where he came under the stimulating influence of Dr Claye Shaw, whose death almost synchronised with his own—and then to others of the L C C asylums and in 1902 he was chosen physician-superintendent to the mental hospital at Warlingham, then in course of construction by the borough of Croydon This hospital which from its inception was furnished with X ray rooms, pathological laboratory, operating theatre and every modern appliance, was the scene of his subsequent work and a constant source of pride to him personally It was there that the word "asylum" was abolished for the first time in the title of a hospital for the care of mental invalids, and Dr Pasmore was always careful to point out that the Cardiff and the City of London Asylum at Stone in styling themselves "mental hospitals" were following the lead given at Croydon The institution justified its description, for its average recovery rate over a period of ten years was somewhere about 42 per cent. Dr Pasmore himself was specially interested in the clinical classification of mental disorder which he based upon ætiological and pathological grounds in the belief that accompanying certain physical states of the body were certain trains of mental symptoms and that from this correlation of mental and physical states it was possible to build up a useful classification of insanity He was insistent that a fully equipped laboratory should be attached to all mental institutions in order that the range of disease might be scientifically investigated During the last few years he lectured on abnormal psychology in an honorary capacity at University College

Those who knew Dr Pasmore personally at Warlingham enjoyed his breezy genial personality, and his presence at the monthly meetings of the Croydon council infused a kindly cheerfulness which was always more than welcome to his colleagues "Of the remarkable efficiency of his management of a large mental hospital," writes one of his colleagues, "there could be no two opinions The sense of system and order infused with personal interest and care, apparent to the official and unofficial visitor to the institution, was as constant as it was striking There could be no doubt that efficiency of control had its counterpart in efficiency of treatment resulting in the large measure of cure or amelioration indicated in Dr Pasmore's periodic reports His death will make his colleagues the poorer by the loss of a personality, often enthusiastic, always considerate and kindly"

Many schemes of social betterment found in Dr Pasmore a ready helper With the late Dr J L Pinnell he founded the University College Working Lads' (now the St Christopher Boys') Club At Ramsgate he started a Hospital Saturday Fund He held the Order of Mercy. His widow, who survives him was daughter of Mr John Screech

PULMONARY EMBOLISM FOLLOWING OPERATION

To the Editor of THE LANCET

SIR,—The interesting article in your last issue by Dr W. A Lister brings out forcibly the relationship between pulmonary embolism after operation and (1) the age of the patient, and (2) the site of the incision The results are fully in accord with what has been observed in practice Important as these points are, however, they are only "accessary after the act" and do not give much clue to the cause of this disastrous complication after what are frequently very slight operations I have known it occur after an aseptic removal of a small toe

I think that great light might be brought to bear on the condition if a series of tests were made before and after operation on the clotting time of the blood I began to make such tests when I was in a position to do so, and found that in about 20 cases the clotting time was diminished about one minute as the result of the operation or anæsthetic This in the normal person is probably beneficial whereas in the person whose clotting time is short a further diminution may lead to the complication referred to In such a patient, if the condition were known beforehand, any cyanosis or impediment to respiration during operation would suggest some modification of the anæsthesia, especially by dilution with oxygen for such time as might be necessary Whether the clotting is due to diminution of oxygen intake or of carbonic acid output does not matter, the treatment would be the same A history of previous attacks ought always to lead to a blood examination, and due attention should be paid not only to typical fatal and non-fatal attacks, but to "pleurisy," "pain in the chest," or 'pneumonia" following within a fortnight of an operation In one family whom I attended, a sister had attacks in three out of four confinements, and two brothers had attacks after operation for simple appendix—one brother two slight ones and the other one fatal in less than five minutes The blood of a daughter of the sister was a rapidly clotting one, and before an operation for appendicitis she was given citric acid as a precaution

I am, Sir, yours faithfully
H A. DES VŒUX.

Ashley-gardens, S W, Jan 14th, 1927

To the Editor of THE LANCET

SIR,—Perusal of Dr Lister's valuable paper prompts me to ask whether there are any other prophylactic measures possible, apart from massage of the lower limbs and breathing exercises The method generally adopted of applying an abdominal binder does very little, in my opinion, to prevent the stretching of the incision, which occurs with each downward movement of the diaphragm Personally, I have no doubt that much firmer pressure can be applied to the incision by means of the "anchor dressing" In this, silkworm gut sutures are passed, either through the whole thickness of the abdominal wall, or through all except the peritoneum, and then tied over the dressing I believe that patients treated in this manner suffer less pain than those treated with a binder, as the "anchor dressing" limits the stretching of the incision

Dr Lister's observations upon the incisions for the radical cure of herniæ, emphasise the importance of firm pressure applied to the operation incision Anchor dressings may be difficult, or impossible, to apply in cases where drainage is required, but here I would like to urge the claims of vaginal drainage, rather than abdominal, in cases of pelvic suppuration I invariably adopt this method of drainage, and have

Obituary.

SIR ISAMBARD OWEN, M D., CAMB & DURH, F R C P LOND HON D C L, LL D

WE regret to announce the death of Sir Isambard Owen, consulting physician to St. George's Hospital, but more widely known as a strenuous and successful pioneer in the cause of higher education The event occurred in Paris on Jan 14th

Isambard Owen was born near Chepstow in 1850, the son of William George Owen, chief engineer to the Great Western Railway, who worked under the famous engineer, Isambard Brunel, after whom he named his son Isambard Owen was educated at the King's School, Gloucester, Rossall, and Downing College, Cambridge, where he graduated in natural science He proceeded to St George's Hospital, where he held the usual junior posts, took the M B at Cambridge in 1876, became curator of the museum, and in 1882 was elected assistant physician At the hospital he lectured on materia medica and clinical medicine, and his out-patient classes were largely attended, for a highly sympathetic manner enabled him to deal with his patients with great shrewdness They enjoyed the particular stress which he would lay upon their family histories, and many valuable lessons in private practice were acquired by those who followed Owen's demonstrations He wrote at this time a small book on materia medica, and both in the out-patient department as later in the wards he paid particular attention to the art of prescribing

In 1883 he was appointed physician to the Brompton Hospital, but resigned the following year, when he became Dean of the medical school at St George's Pre-eminently a man of affairs and an organiser of reforms, St George's Hospital Medical School owes much to his initiative and foresight in this capacity of Dean For example, in 1895 the first lectureship in tropical medicine in London was established there in the person of Sir (then Dr) Patrick Manson who held it until 1908 Before this, as Medical Registrar and Curator of the Museum, his orderly and systematic mind had been much in evidence, and he recatalogued and described the specimens in the Museum on a uniform plan One of his colleagues writes of Owen as a hospital physician, thus "He was a clear teacher and was particularly good on physical signs, which he imitated in a way that his clinical clerks remembered Genial, dignified, and with something of the grand manner, he was a master of the suaviter in modo. His methodical character and complete freedom from any sign of hurry or personal annoyance enabled him to carry through work on many different lines successfully and smoothly, for while Dean and physician to the hospital, in consulting practice, and examining at various universities and licensing bodies, he cheerfully spent much time and energy on schemes for the establishment of a Gresham University in London and a National University in Wales, he really seemed to enjoy drafting official documents and regulations a pursuit in which he was an acknowledged expert" His duties it should be said, were discharged very often under stress of ill-health, for in early days, when travelling with a Napoleonic Prince, he had picked up some form of fever which frequently recurred He was recognised, however, as a sound clinical physician, and was early in the field as an inquirer into the association of disease with habitual intemperance, his work in this direction being done for a collective investigation of a Committee of the British Medical Association, to which he acted as honorary secretary He was appointed an examiner in medicine at different times to the Universities of Cambridge, London, and Durham, at the Royal College of Physicians of London (of which he became a Fellow in 1885), and at the qualifying examination for commissions in the R A M C He was also a highly successful secretary of the Medical Society of London, being largely responsible for the reconstruction of the Society's premises.

But it is in the world of education, as is suggested above by his colleague, that Owen made his mark. His well-known work in connexion with the Universities of Wales of Durham, and of Bristol had its opening phases while he was still on the active staff of St. George's Hospital and practising as a consultant physician In fact it began in his undergraduate days Between the years of 1870 and 1890 three university colleges had been founded in Wales, namely at Aberystwyth, Cardiff and Bangor, and a movement was started for the establishment of a National University of Wales with these colleges, which were receiving Government support, as the constituent bodies A conference was held at Shrewsbury at which the county educational authorities and the Colleges were represented, and Owen's duty in drafting, as secretary, the report of the findings received a remarkable recognition, for the conclusions of the conference as formulated by Owen proved to be substantially the basis of a University charter which was granted in 1893 In 1894 he was appointed senior deputy chancellor of the University of Wales, in which capacity he installed King Edward VII, then Prince of Wales, as Chancellor For the next ten years, while maintaining his deep interest in education and especially in the new University of Wales, he remained in consulting practice in London, lectured in medicine at St George's and was vice-dean of the medical faculty of the University of London But in 1904 he gave up medical practice to accept the position of Principal of the Armstrong College, Newcastle, where his constructive capacities in relation to the higher education again received striking endorsement, for four years after Owen's arrival in Newcastle an Act of Parliament was secured reconstituting the University of Durham in a way which placed the Armstrong College on a proper footing as well as the Durham Colleges, and greatly strengthened the University of Durham and its medical school The close cooperation of the great city of Newcastle with the development of University life in its midst was thus secured This valuable work was done in five years, and in 1909 he became Vice-Chancellor of the new University of Bristol, and threw himself into the task of building up in that great city an institution that was composed of a fusion of three existing bodies whose interests were not necessarily identical The long war intervened at a critical period in the life of the young university, nor did the circumstances of peace bring relief to the Vice-Chancellor's work, which however, he carried on unremittingly, only retiring in 1921 He remained on the governing bodies of the three constituent Welsh Colleges, was knighted in 1902, and again had the honour of installing a Prince of Wales as Chancellor of the University of Wales The Universities of Wales, Durham, and Bristol gave him honorary doctorates He was for many years a member of the General Medical Council representing the University of Bristol

Owen in private life was a particularly charming man, and his great success in affairs owed as much to his powers of sympathy and his conciliatory reasonableness as to his logical grasp of general designs, and his untiring industry He was a good public speaker, and at the various cities where his official duties took him, his social gifts much increased his influence in shaping the plans that he conceived During his career in London he was a bachelor, but, on removing to Newcastle, he married in 1905 Ethel, daughter of the late Lewis Holland-Thomas, of Caerffynnon, Merioneth, by whom he had two daughters

EDWIN STEPHEN PASMORE, M.D., M.R.C.P. LOND., D.Sc., LL.D.

THE death of Dr. Pasmore at the age of 62 years is a heavy loss to the county borough of Croydon where he had been in charge of the mental hospital since its foundation a quarter of a century ago.

Edwin Stephen Pasmore was the son of Capt John Pasmore, and was born at Falmouth in 1864. He studied at the Universities of London, Paris and Brussels, taking his medical degree from University College, London, in 1890 and his doctorate in the following year. After holding house appointments at University College Hospital and Ramsgate he became clinical assistant to Sir William Gowers at Queen Square and from that time onwards was deeply interested in mental welfare and took a leading part in furthering the public mental hospital movement in this country. In 1893 he was appointed pathologist first to Banstead—where he came under the stimulating influence of Dr. Claye Shaw, whose death almost synchronised with his own—and then to others of the L.C.C asylums and in 1902 he was chosen physician-superintendent to the mental hospital at Warlingham, then in course of construction by the borough of Croydon. This hospital which from its inception was furnished with X ray rooms, pathological laboratory, operating theatre and every modern appliance, was the scene of his subsequent work and a constant source of pride to him personally. It was there that the word "asylum" was abolished for the first time in the title of a hospital for the care of mental invalids, and Dr. Pasmore was always careful to point out that the Cardiff and the City of London Asylum at Stone in styling themselves "mental hospitals" were following the lead given at Croydon. The institution justified its description, for its average recovery rate over a period of ten years was somewhere about 42 per cent. Dr. Pasmore himself was specially interested in the clinical classification of mental disorder which he based upon ætiological and pathological grounds, in the belief that accompanying certain physical states of the body were certain trains of mental symptoms and that from this correlation of mental and physical states it was possible to build up a useful classification of insanity. He was insistent that a fully equipped laboratory should be attached to all mental institutions in order that the range of disease might be scientifically investigated. During the last few years he lectured on abnormal psychology in an honorary capacity at University College.

Those who knew Dr. Pasmore personally at Warlingham enjoyed his breezy genial personality, and his presence at the monthly meetings of the Croydon council infused a kindly cheerfulness which was always more than welcome to his colleagues. "Of the remarkable efficiency of his management of a large mental hospital," writes one of his colleagues, "there could be no two opinions. The sense of system and order infused with personal interest and care, apparent to the official and unofficial visitor to the institution, was as constant as it was striking. There could be no doubt that efficiency of control had its counterpart in efficiency of treatment resulting in the large measure of cure or amelioration indicated in Dr. Pasmore's periodic reports. His death will make his colleagues the poorer by the loss of a personality, often enthusiastic, always considerate and kindly."

Many schemes of social betterment found in Dr Pasmore a ready helper. With the late Dr. J. L. Pinnell he founded the University College Working Lads' (now the St. Christopher Boys') Club. At Ramsgate he started a Hospital Saturday Fund. He held the Order of Mercy. His widow, who survives him, was daughter of Mr. John Screech.

Correspondence.

"Audi alteram partem."

PULMONARY EMBOLISM FOLLOWING OPERATION.

To the Editor of THE LANCET.

SIR,—The interesting article in your last issue by Dr. W. A. Lister brings out forcibly the relationship between pulmonary embolism after operation and (1) the age of the patient, and (2) the site of the incision. The results are fully in accord with what has been observed in practice. Important as these points are, however, they are only "accessary after the act" and do not give much clue to the cause of this disastrous complication after what are frequently very slight operations. I have known it occur after an aseptic removal of a small toe.

I think that great light might be brought to bear on the condition if a series of tests were made before and after operation on the clotting time of the blood. I began to make such tests when I was in a position to do so and found that in about 20 cases the clotting time was diminished about one minute as the result of the operation or anæsthetic. This in the normal person is probably beneficial, whereas in the person whose clotting time is short a further diminution may lead to the complication referred to. In such a patient, if the condition were known beforehand, any cyanosis or impediment to respiration during operation would suggest some modification of the anæsthesia, especially by dilution with oxygen for such time as might be necessary. Whether the clotting is due to diminution of oxygen intake or of carbonic acid output does not matter, the treatment would be the same. A history of previous attacks ought always to lead to a blood examination, and due attention should be paid not only to typical fatal and non-fatal attacks, but to "pleurisy," "pain in the chest," or "pneumonia" following within a fortnight of an operation. In one family whom I attended, a sister had attacks in three out of four confinements, and two brothers had attacks after operation for simple appendix—one brother two slight ones and the other one fatal in less than five minutes. The blood of a daughter of the sister was a rapidly clotting one, and before an operation for appendicitis she was given citric acid as a precaution.

I am, Sir, yours faithfully,

H. A. DES VŒUX.

Ashley-gardens, S.W., Jan. 14th, 1927.

To the Editor of THE LANCET.

SIR,—Perusal of Dr. Lister's valuable paper prompts me to ask whether there are any other prophylactic measures possible, apart from massage of the lower limbs and breathing exercises. The method generally adopted of applying an abdominal binder does very little, in my opinion, to prevent the stretching of the incision, which occurs with each downward movement of the diaphragm. Personally, I have no doubt that much firmer pressure can be applied to the incision by means of the "anchor dressing." In this, silkworm gut sutures are passed, either through the whole thickness of the abdominal wall, or through all except the peritoneum, and then tied over the dressing. I believe that patients treated in this manner suffer less pain than those treated with a binder, as the "anchor dressing" limits the stretching of the incision.

Dr. Lister's observations upon the incisions for the radical cure of herniæ, emphasise the importance of firm pressure applied to the operation incision. Anchor dressings may be difficult, or impossible, to apply in cases where drainage is required, but here I would like to urge the claims of vaginal drainage, rather than abdominal, in cases of pelvic suppuration. I invariably adopt this method of drainage, and have no hesitation in saying that convalescence in these cases is much more comfortable and rapid than it would have been were abdominal drainage adopted Again, the advantages of operating by the vaginal route rather than the abdominal, whenever possible, is appreciated by most gynæcologists I think I can safely assert that the tendency amongst the younger gynæcologists is to operate by the abdominal route rather than the vaginal Vaginal hysterectomy appears to be rather out of fashion in these days, but it may be that Dr Lister's paper will bring this into the limelight again

If we can avoid an abdominal incision so much the better Dr Lister has shown us what an important factor it is in the production of pulmonary embolism

I am Sir, yours faithfully

Harley-street, London, Jan 18th, 1927

IMMUNITY TO IMPLANTED TUMOURS

To the Editor of THE LANCET

SIR,—Dr Lumsden's paper in your last issue, on the immunity to implanted tumours, raises many issues for controversy There is, however, one which appears to be of outstanding importance Fig III A and Fig V A of his paper are described as microphotographs of normal in vitro cultures of a mouse carcinoma and of a human carcinoma showing cancer cells They serve as controls to other illustrations In each figure are to be seen scattered cells, entirely separate from one another Now in my experience carcinoma cells do not grow in vitro in this way, they extend out from the implant in the form of continuous sheets or less often columns of cells In Fig III A the cells have the appearance of small wandering connective tissue cells, and in Fig V A of fibroblasts The question raised therefore is, are these cells cancer cells, or are they normal cells derived from the stroma?

The figures open another consideration Referring again to Fig V A, it is certain that, at any rate, some of the cells are fibroblasts, and yet in the illustrations for which this figure serves as a control, all the cells exhibit cytolysis It is remarkable that if anticancer sera are being used, normal cells should also suffer destruction If in a culture of carcinoma normal cells degenerate as well as the cancer cells, it is evident that antibodies against cancer are not being dealt with Inoculated cancers do not, of course, form pure antigens, seeing that they consist of cancer cells derived from some unknown animal mixed with normal cells from the animal from which the tumour was removed

Nevertheless, the question arises, why are normal cells, present in cultures of carcinoma, cytolysed by anticancer serum

I am, Sir, yours faithfully,

J C. MOTTRAM

The Radium Institute, London, W, Jan 17th, 1927

A METHOD OF ELECTRICAL TREATMENT FOR ENLARGED PROSTATE

To the Editor of THE LANCET

SIR,—Respecting the causation of prostatic hypertrophy it is agreed that little is known, but probably a sedentary life with enfeebled circulation in the extremities causing chronic congestion is conducive to the condition It has been estimated that 1 in every 3 men over the age of 60 complains of symptoms caused by an enlarged prostate A catheter life is not a pleasant prospect with the possibility of a major operation, for it seems that prostatic diseases are always to be the province of the surgeon and only inoperable cases are sent to the medical electrician

In the many text-books and articles consulted I have not found any collocation of ideas respecting the electrical treatment of the prostate, information has therefore to be sought in various works. The method I am using will perhaps be better understood if I give here a brief summary of different electrical methods applied in the treatment of prostatic disease

(*a*) *X rays* have been successfully used in this disorder

(*b*) *Diathermy* benefits prostatitis and prostatic hypertrophy and atony of the bladder It reduces pain and is killing to some germs Cumberbatch's excellent work at St Bartholomew's Hospital is well known

(*c*) *High Frequency*—Eberhart states that results from high-frequency treatment of all forms of prostatic disease are extraordinary, 90 per cent of his cases have been apparently cured without a case in which perceptible improvement was not observed He has had positive reduction in cases of senile hypertrophy, and considers high frequency to be vibration causing cellular massage, and as the current increases in frequency and voltage it is capable without an electrode of traversing long distances as do ether waves in wireless

(*d*) *Static Electricity*—Franklinisation—"Morton's wave"—Wm. James Morton, of New York City[1] stated "Static electricity is considered superficial and incapable of penetrating deeper tissues, but electro-statics will give a current that will demonstrably penetrate the human tissues as it can be demonstrated that any other current will penetrate them" But Cumberbatch states "The mode of action of the static wave current is most probably mechanical, the sudden forcible rhythmic muscular contractions aiding the local circulation and the removal of inflammatory products" I would refer to "Electro-therapeutics," by Humphris, under Chronic Enlargement of the Prostate, pp 187–193 Considering the action and excellent results, one must think of Morton's wave as a 'prostatic squeeze," inter alia emptying the vesiculæ and prostatic follicles I am unable to find any reference to prostatic treatment by faradism, possibly for the reason that it has not been used as strong currents cause pain and disgreeable sensations

In view of the results obtained by Morton's wave by tuning and regulating the current, I cause faradism to give an effect similar to Franklinism—Morton's wave Be it remembered that in Morton's wave a spark which occurs at some distant part of the necessarily closed circuit causes a steady current of successive electrical impulses, blows, or tugs

I use a Smart-Bristow coil in which the current is derived from the secondary coil, and its strength is varied by sliding the iron core in or out of the primary coil The secondary coil is so constructed (bound with somewhat coarse wire) as to produce painless muscular contractions, these contractions are governed by the switch—either one, two, three or four divisions of the secondary winding—and the iron core or plunger, and I tune them (the contractions) rhythmically by placing a metronome interrupter in circuit The metronome I time to synchronise with the heart-beats An ordinary zinc electrode is inserted in the rectum, but preferably I would use the rectal electrode designed by Dr St Aubyn Farrer, a broad, flat electrode is placed over the hypogastric region, but it can be applied anywhere on the abdomen If there is any objection from the patient to inserting the electrode in the rectum, confidence can be given by the use of a small, flat electrode on the perineum

The treatment is continued for 10 to 15 or 20 minutes Great benefit has been obtained, micturition has become less painful, not so frequent by day and night, and in a stronger stream, there is a feeling of lightness in the perineum and prostatism begins to disappear I have applied this treatment to a hard prostate, but should expect an even better result with an enlarged soft vascular prostate

A static machine with its working complements is costly to instal and for its current depends largely upon the weather. All the apparatus I use can be obtained for quite a modest sum. A word of warning is here necessary—galvanism must never be used; the metronome will only interrupt or reverse the direct current but will not do away with its chemical or electrolytic action. This can be proved by means of pole-testing paper. It is also unwise to use a faradic current attached to a galvano-faradic battery, as sometimes there is a leakage of direct current. The Smart-Bristow battery should be used instead. Faradism cannot produce electrolysis, but the ordinary faradic apparatus has usually fine windings which cause painful tetanic muscular contractions. It should always be ascertained that terminals and switches are properly adjusted so as to ensure a smooth and even current.

---

FREDK. WM. ALEXANDER.
Teddington, Jan. 18th, 1927.

TREATMENT OF TUBERCULOSIS BY MR. SPAHLINGER'S METHODS

To the Editor of THE LANCET.

SIR,—I am obliged to Dr. Nelson for his courteous reply to my letter. Although it now appears that Thomas Henry Allen's case was indeed among the Spahlinger Latham records at St. George's and that Dr. Nelson excluded it from his survey, it gives me much pleasure freely to acknowledge that the circumstances surrounding the exclusion completely exonerate Dr. Nelson from any suspicion of bad faith. Arguing from the record alone Dr. Nelson was quite justified in concluding that Allen had never had tuberculosis. There are nevertheless certain facts which point with emphasis in the opposite direction. Allen himself insists upon the emaciation and his wife bears eloquent testimony to a hæmoptysis. At the French Hospital we regarded him as an early but rapidly progressing case, and our view was supported by several competent physicians, including Latham himself. When under the circumstances mentioned in my last letter I was requested to remove Allen and Grace Edney from the French Hospital, I asked Latham if he would take them and put them among the Spahlinger cases at St. George's. He came to the French Hospital where he examined these two cases and agreed to do as I suggested. No one with a recollection of Latham, however slight, could suppose that he would have accepted Allen had he not been satisfied that the case was clinically one of tuberculosis; and an affirmative from such a source is worth many negatives. Moreover, if Latham had afterwards come to the conclusion that Allen was not a case of tubercle, it is not only curious, it is astounding that in the many conversations which we had together on the subject of the Spahlinger treatment he should not have mentioned the fact. He certainly never did.

It is very kind of Dr. Nelson to invite me to study with him the records at St. George's. But if only for the reason that my acceptance might be misconstrued into a doubt of his veracity, I must beg him to have me excused.

En revanche, let me suggest to Dr. Nelson that if he is really desirous of estimating the value of the Spahlinger treatment he should arrange to accompany me to Geneva, where I will undertake to show him enough in records and living testimony to convince him that at its lowest it is the part of a wise physician to preserve an open mind on a subject which has been so sadly overlaid with prejudice and *parti pris*. Your obedient servant,

Harley House, Jan. 18th, 1927. LEONARD WILLIAMS.

ULTRA-VIOLET RADIATION

To the Editor of THE LANCET.

SIR,—No definite technique has as yet been established in ultra-violet therapy, and as the alternate exposures with carbon and mercury arcs adopted by Drs. Punch and Wilkinson were somewhat unusual, I had hoped to elicit the theory on which their technique was based. Beyond stating that the carbon arc is richer in the near and more penetrating ultra-violet rays and the mercury vapour in the far ultra-violet rays no explanation is offered. It is difficult to see why near and penetrating ultra-violet rays should be indicated at one exposure and a greater concentration of far ultra-violet which have very little penetrating power (in fact, those below 2400 A° units do not penetrate at all) should be indicated at the next exposure. It might surely be assumed that as the treatment proceeded more and not less penetrating rays were necessary.

On the question of local treatment I asked why the tungsten arc was used in preference to either of the mercury-vapour lamps and not to the Kromayer alone, which admittedly might be inconvenient for a large area. The authors make no comparison between the air-cooled mercury vapour and the tungsten arc. Personally I have not noticed any superiority in the tungsten arc over the mercury vapour for softening any tissue, nor am I aware that anybody has yet demonstrated that the different concentration of energy along the tungsten arc spectrum is likely to give local effects superior to those obtained with the mercury vapour. In recent articles I have noted a tendency towards the use of a number of lamps on the same patient, no explanation (except where the area to be treated makes it obvious that one lamp was more suitable than another) being offered. I had hoped to find some reason for this tendency.

I am, Sir, yours faithfully,
London, W., Jan. 11th, 1927. M. WEINBREN.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council held on Jan. 13th, Sir Berkeley Moynihan, the President, in the chair, Princess Mary, Viscountess Lascelles, was elected an Honorary Fellow of the College in recognition of her work in connexion with the nursing profession and hospitals.

Sir Berkeley Moynihan was elected to represent the College at the celebration in London of the centenary of the birth of Lord Lister, which falls on April 5th.

The Diploma of Fellow was conferred upon Clifford I. N. Morgan, M.B. Lond. (Cardiff and St. Bart.'s).

Diplomas of Member were conferred upon J. H. Couch, M.B. Toronto (Toronto), T. M. Jones, M.B. Liverp. (Liverpool), and Joyce McConnell (Royal Free Hosp.).

The Licence in Dental Surgery was conferred upon F. H. Channon (Guy's).

The undermentioned diplomas were conferred (jointly with the Royal College of Physicians) upon the following candidates:—

DIPLOMA IN PUBLIC HEALTH.

M. L. Bahl, Marjorie Broadbent, Madeleine H. Clarke, Kathleen Davies, Muriel Davies, J. Fanning, Dorothea C. Forbes, W. L. Forsyth, L. I. Henzell, K. H. Kamakaka, Dorothy L. M. Keats, A. H. Kynaston, A. S. MacNalty, S. M. Mallick, B. S. Manghirmalani, G. O. Mitchell, A. G. Morison, B. R. Nisbet, Helen O'Brien, Evelyn D. Owen, A. C. T. Perkins, Q. M. Said, J. B. Samson, T. G. N. Stokes, C. I. Streich, and Elsie Warren.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

M. Abd-el-Hakeem, P. Banbury, E. A. Bennet, J. Bennet, A. G. Duncan, Isabella A. Gillespie, J. Heron, F. L. McDaniel, H. B. Porteous, and H. T. Retallack-Moloney.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

R. T. Desai, L. W. Johnston, O. F. A. Krause, G. S. Macdougall, J. E. G. McGibbon, N. M. Rao, and T. Williams.

ROYAL NAVAL DENTAL SERVICE.—At the recent competitive examination for entry into the Service, the following candidates were successful:—

William Edward Loftus Brigham, Leslie Foster Fairey, Sidney Mawer, Frank Drummond Manners, Leonard Austrim Moules, George Baker, William Charles George Ford, Leslie Robert Armstrong, and Harold Macklow Hill.

ROYAL SOCIETY OF MEDICINE.—The Section of Surgery is arranging to hold a debate on the Treatment of Cleft Palate on Wednesday, June 1st, at 5 P.M. Sir James Berry will open the debate, Mr. Grey Turner will speak second, and a large number of other surgeons will take part. It is proposed that all speakers shall present statistics and show cases to demonstrate the speech result.

At the quarterly meeting of the Directors of the Naval Medical Compassionate Fund, held on Jan 18th, Surgeon Vice-Admiral Sir Joseph Chambers, K C B , C M G , Medical Director-General of the Navy, *in the chair*, the sum of £135 was distributed among the several applicants

University of Cambridge —The third annual Sims Woodhead memorial lecture will be delivered in the Arts School, Bene't-street, Cambridge, on Thursday, Jan 27th, at 5 15 P M , by Mr W McAdam Eccles, whose subject will be Alcohol in the Light of Modern Research Points Accepted and Disputed The Vice-Chancellor will preside The memorial secretary is Mrs D Moore, Cambridge-road, Histon, and seats will be reserved on a *train from London*

Amalgamation of Army Nursing Services —Queen Alexandra's Imperial Military Nursing Service and Queen Alexandra's Military Families Nursing Service have been amalgamated by Royal Warrant The combined service will be named " Queen Alexandra's Imperial Military Nursing Service," and its members will wear the existing uniform and badge of the Military Nursing Service

Gresham College —Four lectures entitled a Survey of the Public Health will be delivered at 6 P M on Jan 25th, 26th, 27th, and 28th, by Sir Robert Armstrong-Jones, at Gresham College Basinghall-street, London, E C The lectures will be based on the report for 1925 of the Chief Medical Officer of the Ministry of Health, and admission will be free

Extension of Plymouth Mental Hospital —Plymouth Town Council has decided to spend £110,000 upon the first instalment of necessary extensions of Blackadon Mental Hospital , the entire scheme is expected to cost £216,000 The works now authorised include an admission hospital, an infirmary , and a nurses' home

Coventry Hospital —A cheque of £21,650, made up largely of weekly contributions by work-people, has been handed over by the Coventry Hospital Saturday Committee *to the local hospital*

Accidents and Inquests in Leeds —The annual report of the Leeds city coroner shows a big increase in the number of deaths due to accidents on the road In 1926 the number of inquests held in these cases increased from 50 to 77 The total number of cases reported to the coroner was 682, and 631 inquests were held

Wolverhampton Hospital —The Wolverhampton and Staffordshire Hospital is about to be enlarged by the erection of new out-patient and casualty departments and the provision of two children's wards, at a cost of £16,000 A suite of rooms separate from the out-patients' department, is to be provided for accidents and casualties, and the present 20 cots for children will be doubled

Fellowship of Medicine and Post-Graduate Medical Association —On Thursday, Jan 27th, the opening lecture of the new series on Emergencies in Medicine and Surgery will be delivered by Dr L S Burrell at 5 P M at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square The subject is Hæmoptysis On Tuesday, Jan 25th at 2 P M Mr Victor Bonney will give a special demonstration for the Fellowship at the Chelsea Hospital for Women On the same date, at 3 15 P M , Dr Malcolm Donaldson will give a lecture on Salpingitis at the Royal Northern Hospital These lectures and the demonstration will be open to members of the medical profession without fee From Jan 31st the London School of Dermatology (*St John's Hospital*) will hold a four week's clinical course consisting of instruction in the out-patient department and bi-weekly lectures Classes in pathology will be arranged if required From Feb 7th the London Lock Hospital will give a four weeks' clinical course in Venereal Diseases, together with a formal series of lectures Starting on the same date there will be a two weeks' combined course in Diseases of Children in which the Paddington Green and *Victoria* Hospitals will participate , there will be morning and afternoon sessions The Royal Northern Hospital is *holding* a course for general practitioners for one week from Feb 21st, no fee will be charged The Fellowship also arranges for courses in obstetrics and anæsthetics Arrangements can be made for obtaining appointments as clinical assistants at the Samaritan Hospital Syllabuses of the special courses and copies of the programme of the general course and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

Royal Institution —On Friday, Jan. 28th, at 9 P M , *Prof* E P Cathcart will lecture on the Physique of Women Employed in Industry

Donations and Bequests —Mr. Robert Bower Sharp, Fernhall, Broughty Ferry, jute merchant, besides bequests to employees, gave £5000 to the Royal Victoria Hospital, £3000 to the Sidlaw Infirmary, £2000 to the Convalescent Home, Barnhill, and £3000 to the Dundee Sick Poor Nursing Society

Dental Beds in a General Hospital —The Royal Dental Hospital has arranged for 12 beds in a London general hospital to be at its disposal for use by such of its patients as are in need of hospital treatment The intention is that dentists from the Royal Dental Hospital shall perform their most serious operations at the general hospital so that patients may be properly cared for both before and after the operation

Royal Alexandra Hospital for Sick Children In memory of Queen Alexandra, it has been decided to build a new block at the Royal Alexandra Hospital for Sick Children, Brighton, at a cost of £10,000 The new block will include an irradiation clinic, an up to date operating theatre, a room for anæsthetics, and additional accommodation for the resident medical staff It is hoped to complete the work in 1928

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning
